Mosher has devised an instrument for cutting a tooth plate, but this would not have been practical as the plate had become so thoroughly embedded. An application of silver nitrate was made to the ulcerated surface and the patient

fed hot milk until all inflammation had subsided. The last time the patient was seen he was in good condition.

NON-OPAQUE FOREIGN BODIES:

In children the most frequent and fatal forms of foreign bodies which find lodgement in the food and air passages are the various kinds of grains and nuts, such as corn, beans, peanuts, etc. Such substances are more likely to be followed by immediate death, or later develop violent inflammatory reaction than the inorganic substances. The roasted peanut is peculiarly irritating and usually produces a train of symptoms of its own known as "peanut bronchitis". The x-ray and fluroscope do not give us aid in locating this class of foreign bodies which they afford in the opaque form, yet they are often invaluable in determining the pathology resulting and should always be used if the time can be taken. The history we get in these cases is often vague, but physical examination by a physician of experience will often determine the presence of the foreign body. By carful study of the physical signs it can be determined what portions of the lung are being deprived of air and drainage and from this the almost exact location of the foreign body can be deduced. The bronchoscopist should always study these cases with the man in general medicine and the roentgenologist if he hopes to serve his patient best, at the same time gaining some knowledge of these cases.

Case IX. Referred by Doctor Harris of Bloomington, Indiana. A boy five years of age while feeding chickens aspirated a grain of corn into the trachea. Doctor Harris was called at once and finding the child in spasms, with coughing and dyspnea, he immediately brought the child to the Methodist Hospital. Everything was ready when the patient arrived. Careful ether anesthesia was given, a bronchoscope introduced per oral and a large grain of corn found lodged in the right lower lobe bronchus. It was grasped with forceps and brought up to the glottis with the 'scope. In an effort to bring it through the glottis a spasm was caused which seemed to be fatal. A quick tracheotomy was done and the grain of corn removed. Artificial respiration restored normal breathing after considerable effort and the patient recovered after a few days in the hospital.

Case X. Is almost exactly similar to the last. A grain of corn aspirated by a child five years of age while playing with corn. Doctor Tyndall of Shelbyville was called at once and finding the patient with frequent spasms of coughing and cyanotic, took him in his car and made a hurried trip to the Long Hospital in this city, after notifying my office by long distance. When the patient arrived he was so cyanotic that anesthesia was unnecessary. With the bronchoscope the grain of corn was found in the right middle lobe bronchus. Just as we were about to deliver it one of the physicians present, in his desire to see it brought out, kicked over the battery, breaking the electric connections and leaving us in the dark. When the lights were turned on in the operating room our patient was apparently dead. A stab tracheotomy was done and with artificial respiration the patient was restored. It is unnecessary to state that this case caused us a few anxious and dramatic moments.

Case XI. A boy four years old, referred by Doctor Little, was seized with spasms of coughing and choking while at play. The symptoms became so alarming that Doctor Little was called. He suspected a foreign body and possibly a grain of corn, as the child had been playing in a corn field. The patient was brought to the Methodist Hospital. Physical examination of the chest clearly indicated a foreign body, probably on the left side. Characteristic symptoms of wheezing respiration, dyspnea and coughing were present in a marked degree, with a temperature of 101 degrees. A bronchoscope examination was made per oral lasting twenty minutes without being able to locate the foreign body. After a few days' quiet in bed an x-ray examination was made by Doctor Beeler and the report said, "There is a shadow on the left side which is rather suspicious, but not positive." On the second bronchoscopic examination we found the left lower lobe bronchus swollen and partially filled with exudate. After clearing the tube, a flat white grain of corn was found adhering close to the mucosa. It was removed through the 'scope, the operation requiring ten minutes. The lung cleared up in a few days.

Case XII. A boy fourteen years of age, the patient of Doctors Stayton and MacDonald. Doctor MacDonald had obtained a vague history of the aspiration of a peanut. This child was so ill that we had some hesitancy in making a bronchoscopic examination at the time—temperature 104½ degrees and pulse 140. The pleural cavity had been aspirated for pus. A bronchoscopic examination was made, however, as the discovery of a foreign body seemed the only hope. The right lower lobe bronchus was found inflamed and full of exudate. After clearing the tube by suction and sponging, one of the smaller bronchi was found to be filled with what seemed to be a portion of a peanut kernel. On removing it with forceps the abscess broke, filling the bronchoscope with pus. After a quantity of pus was coughed out the patient's breathing became better. This was followed by a rapid fall of temperature and pulse and gradual recovery took place.

Case XIII. A child aged eleven months was referred from near Frankfort, Indiana, with the statement that a bean had been aspirated the day before. The child's breathing was labored and its appearance cyanotic. An x-ray was made by Doctor Beeler at once. The body being non-opaque, the x-ray did not show its location. Bronchoscopic examination under light ether anesthesia revealed the bean in the right middle lobe bronchus. It was embedded so tightly in the irritated tube that we could not dislodge it with any forceps at our command at that time. A tracheotomy was done and a tube put in, hoping we might have another chance, but the child died that night from dyspnea.

Case XIV. A penny removed from the esophagus of a child three years old. Nothing unusual in the case.

Case XV. A child six months of age swallowed a twig of a Christmas tree. This was removed from the middle third of the esophagus through the esophagoscope.

THE PHYSICIAN

"THOU SHALT NOT KILL"*

BY FRANK B. WYNN
INDIANAPOLIS, INDIANA

At first thought the commandment which is the title of this essay would seem to be wholly inapplicable to practitioners of medicine. Yet even the most cursory study of their professional conduct will reveal many who are innocently, ignorantly or even criminally responsible for the loss of life. These sins are more often negative than positive. Professional ignorance, carelessness or selfishness does not absolve one from responsibility in the performance of duty. Since the care of life is placed upon our shoulders, this imposes the most serious obligation to bring to bear all the agencies within our power for the relief or cure of the patient. Critical observation impresses one that even good men, measured by the ordinary standards of conduct, fail to comprehend the gravity of this responsibility.

First, how often are we guilty of negative sin in public health matters—carelessness or oversight in reporting contagious and infectious diseases. The management of almost every case of infection, acute or chronic, carries with it the personal obligation of the physician to put out the warning signal—to give always without money and without price the instructive knowledge which will prevent further extension of the disorder. What fearful responsibility rests upon us too, as possible carriers of infection. In this vast altruistic program let us not be discouraged by the indifferent attitude of the public so quick to question the wisdom or sincerity of our action. We should rather with unabated fervor continue our support of all public health movements. To do less would constitute contributary negligence in the taking of life.

Vaccine treatment (and its kind) constitutes the dominant therapeutic fashion of the day. The innumerable biologic products of the great pharmaceutic houses, with their enticing and suggestive literature, often lead the unwary astray. Novices who do not fully understand the conditions warranting such treatment rush to its use with innocent enthusiasm but in ignorance of its dangers. One should remember that the injection of a foreign protein into the body is always a serious matter. Future medical history will undoubtedly record that through the cupidity of commercial houses, members of the medical profession have often been led astray in this matter of vaccine administration. Aside from the serious harm and danger to life arising from their improper use, it is humiliating to the good name of medicine to have been duped by a grasping commercialism.

In no phase of medical practice are the sins of omission so common as in the realm of diagnosis. It is a natural error and there are mitigating circumstances oftentimes. The busy practitioner especially is likely to fall into the habit of drawing hasty conclusions from subjective phenomena. A patient comes with a ready-made diagnosis, only asking for a prescription. It is polite and so easy to follow his lead and prescribe a symptomatic remedy. For headache bromides may be given only to find a few hours later uremic convulsions, which might have been warded off by proper measures at the right time. Or pain in the epigastric area or right lower quadrant is permited to go with a prescription for "biliousness" or "intestinal indigestion". Golden hours are frittered away when prompt surgery might relieve with success a condition which later becomes hopeless. Not less culpable is the case diagnosed as appendicitis and operated immediately, when the day following reveals the essential condition to be right sided pneumonia with reflex abdominal pain. Or what sin of omission is more common than prescribing a cough sedative to a person with an acute "cold" giving assurance that prompt recovery will take place. A month later the patient returns running temperature elevation and having well marked signs of acute pulmonary tuberculosis. Again, surgical experience and pathology have long since proved incipient cancer curable by radical measures. Yet how common is procrastination until metastases proclaim the doom of the patient. The disposition we all acquire with maturing experience and years to place greater faith in nature's capacity to combat disease should never find justification in the treatment of cancer.

*Fifteenth of the series of articles by Dr. Wynn appearing regularly in THE JOURNAL.

When and *when not to operate* are questions which perplex both special and general men. Honest differences of opinion prevail. Inexcusable procrastination on the one hand and presumptious radicalism on the other are unseemly and often disastrous to the interests of the patient. A few well established standards have been worked out, disregard of which is apt to be followed by serious or fatal results. In some surgical conditions temporizing is a sin just as in others delay is a virtue. In fulminant appendicitis immediate surgical attack is the proper procedure; but in acute gall-bladder disease cautious delay and later operation will generally enhance the patient's prospects of life. Procrastinating in cases of chronically infected tonsils giving a history of rheumatic and neuritic attacks, is just as inexcusable as to radically invade tonsilar tissue when there is constitutional and local evidence of acute infection. Operation in the latter case is very apt to pour virulent septic and toxic material into the blood and lymph streams, often followed by acute pulmonary, renal or cardiac involvement of grave significance. Even a minor operation like the wholesale extraction of teeth which are pyorrheal is sometimes followed by local organic implantation. Hence in these cases it is rarely advisable to extend the extraction over two or three sittings.

In other cases where multiple foci of infection exist it often requires large self-control and moral force on the part of the surgeon to abstain from wholesale ablation of pathologic lesions, remote from each other. Patients themselves insist upon having the whole field cleared at a single operative attack. Under such circumstances the operator should always lay close to his conscience the fact that every additional focus of infection attacked surgically adds greater shock and larger possibilities of spreading infection. In practice one often observes in one surgical procedure, operation upon the appendix and the female adenexia. The propinquity of parts makes this feasible. On the other hand the simultaneous attack upon septic foci remote from each other—say the gall-bladder and tonsils—subjects the patient to infinitely greater risks. It is a species of gambling with the protective forces of the body which good surgical judgment will seldom tolerate. Instead of such surgical adventure it were wiser to be less brilliant and exhibit keener conscience for the saving of life.

The chief topic of discussion in this essay is that of criminal abortion. This crime has existed in all ages. It has been more prevalent in civilized countries than among primitive races. Even in our own land it has been a matter of frequent observation that the families of our grand parents were larger than in our own day—partly due to their physical sturdiness, partly because less given to the modern sin of preventing conception, and most of all from the fact that the public conscience was keenly opposed to the interruption of the course of gestation. What are the underlying factors which have brought about this change of attitude toward begetting and bearing children and home-building?

The rapidly increasing urban population constitutes the chief foundation stone of this crime. The artificial life which it begets makes children inconvenient. Among the leisure class where childbearing should be prolific, the feminine patrons of luxury and comfort give way to the spell of indolence and selfishness. The consuming thought is not how they may become the matrons of large and healthy families but how they may avoid these physiologic triumphs and substitute the ennervating social life with its irregularities and excesses.

And since this is the goal toward which the extravagances and fashions of the age point, the young man of moderate means hesitates to face the responsibilities of marriage. Or should he do so he is driven by the fear of large social demands and the financial burden of maintaining a large family, into accepting and practicing the common sex sins of preventing conception or resorting to abortion.

Near akin to the social errors of the day in feeding these vicious practices is the restless spirit of the age—the morbid craving for sensational excitement, quite inconsistent with the practice of domestic virtues. To be reckoned with also is the habitation question. Modern apartments have rapidly usurped the place of the cottage and home. Apartments are not suited for the rearing of children; and furthermore the little ones are not wanted. So does commercialism join hands with vicious social and sex-life in the promotion of abortion.

That public sentiment has become tolerant of the practice of abortion is borne out in the experience of every general practitioner. As the newly married couple enters the private consultation room, one hopes that they have come to express joy over conception and the prospect of parenthood. But not so. Their whole demeanor is apologetic. A flimsy array of excuses is offered why she should be "brought around"—her friends will make sport of her for having a baby so soon; it will interfere with numerous social engagements; she is not strong, etc., etc.

In listening to such narratives it was always difficult for me to repress indignation. What is particularly irritating is that they so often assume an air of confidence that the doctor will yield to their importunities. Curiously it does not seem to occur to them that they are asking the physician to engage in a criminal act; and that on their own part they are guilty of murderous intent based upon the most sordid selfishness.

Here is one of the most difficult and delicate questions which the general practitioner must face. It is not merely a question of ethics to the physician—it is a problem of vital concern to the morals of the community, the health and happiness of the citizenship and the growth and stability of the State. The practice is undermining the very foundation of our national life—the home. Legislation will not correct the immoral tendency. The law never has been able to make substantial progress in bringing professional abortionists to a reckoning. Larger reform will result from the profession seeking to purify the fountainhead of this vile stream. It is for us in public and in private to show on the one hand the physiological wrong and the grave dangers of such practices; and on the other to hold up the ideals and rewards of the home with children to make secure the marital union—bringing new burdens it is true, but greater rewards in the end. It is for us to make plain that the violation of the physiologic law is not merely a crime. It brings upon its perpetrators a restless and unsatisfied life. It is the opening of a Pandora box of evil spirits, spreading disaster in the household—selfishness, cynicism, sex-suspicion. As the sexual fires burn low, marital infelicity flames high. The victims pass down life's journey without children or grand-children to lighten their burdens or brighten the pathway. Some have the wisdom to try to retrieve their moral losses by adopting children—an experiment which generally yields splendid results.

Here then is laid upon the profession a tremendous responsibility. Who is in a position to render such valuable service for the physiological and social good of the race? Is there not deep need of a quickening of the medical conscience upon this question?

I cannot better close this appeal than by quoting as best I can from memory an experience of early student days. It was in the office of a "Practitioner of the Old School" where I did a little study and learned more in practical wisdom. One day we noticed approaching a young man and his wife—only recently married. They belonged to the so-called aristocratic society of the little city. The doctor (blessed be his memory!) divined the mission of the young couple. Turning to me he said: "You take a seat in the apothecary shop, leaving the door ajar into my consultation room. Then listen with both ears how I handle this situation."

After ushering them into his private office the young bride opened the conversation. "Doctor, it is two months since we were married. I have not menstruated and have the most intense aversion for food. Here I am with any number of social obligations, an elaborate trousseau, and should be having the time of my life, but I get no pleasure out of these things. We were planning a trip west next month but I do not feel like going. You know I have not been well for a year or two. Mother is terribly worried and says if I should be in a family way it would wreck my health."

She paused a moment which gave the doctor a chance to shift the current of thought which he did in this deft manner: "As I recall it, Catherine, you are now past twenty. You know I was present at your first birthday celebration and gave you your first spanking. It was a great occasion. You stirred up a terrible commotion. One time I thought you done for—blue around the 'gills' and no sign of breath! I poured cold water down your spine. You thought that an outrage and yelled like an Indian. It was a close call. You've been a lot of trouble to your folks all these years but I guess they think you worth it. Aren't you glad your mother didn't do anything to interfere with Nature's course seven months before you were born? If she had, it would have been wrong and you would not be here this minute.

"By the way, had you noticed in the morning paper that the Lambreths have separated and she is suing for divorce? What a pathetic situation! They have proud family names, wealth and social position but their union has proved a failure. Why? They started wrong. They bowed before the shrine of 'high life', worshiping the idols of selfishness, luxury and ease. They did not want children who would interfere with their indulgences. After a few years' pursuit of these things she yielded to maternal yearning for parenthood, but Nature so often balked, refused to bear fruit. Note now, the melancholy train of her physical misfortunes: Measures to prevent conception; criminal interruption of the course of pregnancy; diseases of the female organs secondary to these practices; repeated surgical operations without relief; chronic invalidism; peevishness, melancholia and sex-suspicion. There has been the development on his part of cantankerousness, cynicism, and sex-wandering. And now the climax has been reached in this divorce proceeding. My young friends, what is the thing which would have spared these unhappy people this sad fate? Children would have welded their lives into a holy union, with exalted purposes and aims. I have not the wealth of the Lambreths but I am the proud possessor of three precious gems: Ruby with her pink skin, puckering dimples and roguish chatter; Opal with her iridescent temperament as changeable as sunshine and showers in April; and Pearl, the gem of quiet steadfastness and purity! Ah, what a joy to our lives are these three children. From sleepless nights, uncollected accounts and harrassing cases I come home grouchy.

Things are not helped by my wife being irritable over domestic routine and telephone annoyances. And so we cross swords in a little family spat, but how quickly it is all forgotten and forgiven in the joy we find in our children. They make life as it runs on worth living. And so I look forward to you young people getting the same happiness out of the bearing and rearing of children that we have done." Rising to depart Catherine said: "Doctor, we will follow happily what you have advised."

The interesting sequel to this interview came three years later. They were again in the physician's private office, leading a beautiful, little boy. With heart palpitating and tears streaming down her face the young mother pointed to the lad saying: "Oh, doctor! Suppose we had carried out our selfish, carnal impulses!"

NEEDLE IN ABDOMEN SIMULATING TUBERCULOSIS OF THE HIP

ARTHUR A. RANG, M.D.
WASHINGTON, INDIANA

There are a great number of cases reported where pins, needles or fragments of needles have been found in various parts of the body, or have made their appearance under or through the skin in many different localities. Many of these reports are offered by the laity, the foreign body having been removed without surgical assistance, and often the mode of entrance is undetermined.

The following case is presented because of the peculiar history, the gravity of the situation developed, in contrast to that usually resulting from a needle being present in the tissues, and the very interesting diagnostic features developed.

M. G., age 12 years, was presented for treatment of a fistula opening over Pouparts' ligament, midway between the anterior superior spine of the ileum and the pubis, with the following history:

Family record negative, except her paternal grandfather, who had tuberculosis. In August, 1913, she complained of a sudden pain in the lower right quadrant of the abdomen, which seemed deep and in the region of the appendix. The pain increased in severity and she walked with a limp, on the toes of her right foot. The family physician was called and made a diagnosis of appendicitis, which was concurred in by a consultant, and an operation was advised. This was refused by the parents and the girl was removed to a sanitarium in another city, where the case was treated expectantly. During her stay in the sanitarium she ran a continuous temperature and had night sweats. Her right leg was drawn up on her abdomen and remained so for two weeks, after which it gradually straightened out, but she was unable to walk on it without a limp for several months. She suffered considerable pain in her right hip, became emaciated and showed very little improvement until February, 1914, when an abscess pointed and evacuated itself over the crest of the right ileum, and immediately the pain and soreness in the hip began to subside. This drainage persisted for several weeks and then closed, opening a short time later with the sinus over Pouparts' ligament, which has continuously drained since then. Her weight increased and her general health greatly improved.

In the last six years she has been treated by different doctors with different diagnoses, mostly built up on a tubercular hypothesis. Among these were tuberculosis of the hip, and tuberculosis of the spine with a psoas abscess, both of which were possible with the symptoms complained of by the patient and objective symptoms presented. Without a radiogram neither diagnosis could be disproved.

In my first consideration of the case, I was impressed with the idea that the original condition must have been appendicitis, or an abscess in the territory closely associated with the appendix, and this idea was strengthened by my respect for the judgment of the physician who first saw her and made the diagnosis of appendicitis. To determine the extent, size and origin of the fistula, and the condition of the bony structures under suspicion, the fistula was injected with bismuth paste and the patient radiographed. The result was a distinct surprise, as the radiogram showed what was apparently a pin with a large head, located within the abdominal cavity near the normal location of the appendix. Two weeks later this foreign body was removed at operation and proved to be a needle, minus the eye, heavily coated on one end with concretions, which gave it the appearance in the picture of having a head. It was thoroughly embedded in a mass of scar tissue within the abdominal cavity. Following the operation a slight fecal fistula developed and continued intermittently for three months and then closed permanently.

With the history of her initial attack, with the fact that all of her bony structures appear normal in the radiograms, and with the advent of the fecal fistula on opening the external aspect of the scar mass, it seems safe to presume that this needle gained entrance through the gastrointestinal tract, to have perforated the intestine in the region of the appendix, and to have formed an abscess simulating a true attack of appendicitis, afterwards becoming enclosed in the scar mass resulting from the abscess and becoming heavily coated with concretions.

In this case, again, the importance of a radiogram in obscure conditions, and the very helpful information to be derived therefrom, is emphasized, and in this particular instance was absolutely essential for a diagnosis.

THE SCHICK TEST AND THE ADMINISTRATION OF TOXIN-ANTITOXIN FOR THE PREVENTION OF DIPHTHERIA

While the last twenty-five years have witnessed a reduction in the mortality from diphtheria, largely as a result of the prompt and sufficient administration of antitoxin, a reduction of from 150 per 100,000 of the population to 21 per 100,000 of the population, it is apparent, as stated by the Bulletin of the Department of Health of New York City, from which we quote, that we have almost approached the control of the cases of this disease by the old method of disinfection and antitoxin administration. As the statistics of the last decade show, there has been practically no reduction in the morbidity of diphtheria. The limitation of control is due to the fact that many susceptible individuals contract diphtheria not by exposure to cases ill with or convalescent from the disease, but from carriers or persons in apparent health who harbor diphtheria bacilli in their throats or noses. It is well known that a large percentage of diphtheria cases have not been in contact with known cases of the disease. Furthermore, many mild cases of diphtheria, presenting evidence of only reddened throat or tonsillar exudate, as well as many cases of well marked diphtheria, are unrecognized and untreated. These cases contribute in no small way to the infection of susceptibles. Therefore, a still further control of diphtheria depends upon the determination of which individuals are susceptible and then to render them immune, for in spite of all rules and regulations of reported quarantine, educational propaganda, administration of antitoxin, school medical inspection, improved hygiene and sanitation, there still remains the inability to isolate and control carriers in these cases. As a result of numerous laboratory experiments and clinical observations it has been established that the Schick test provides a simple, convenient and reliable means for determining the susceptibility or immunity of individuals to diphtheria, and that the administration of three doses of toxin-antitoxin, given one week apart to susceptibles, will protect the vast majority of them—90 percent or more—against diphtheria, perhaps even during their lifetime. The Schick test and the administration of toxin-antitoxin offers such great possibilities, that the Indiana State Board of Health proposes that all children entering school for the first time be immunized at once. Children entering boarding schools or homes for children also should have the Schick test made, and be immunized if susceptible. The material for the Schick test may be obtained from the large biological supply houses, the technique is simple, and the reactions are dependable if carefully controlled. The toxin-antitoxin preparation for immunization purposes also is sold in packages for use and is inexpensive. Comprehensive information concerning the subject will be furnished on request by the Indiana State Board of Health.

DR. HUGH CABOT'S MEDICAL SOCIALISTIC SCHEMES FOR MICHIGAN

If anyone thinks that we are borrowing trouble when we talk about the possibilities of State Medicine and the evils resulting therefrom, let him digest the statement made by Dr. Hugh Cabot, the new dean of the Medical Department of the University of Michigan, who is quoted in the daily papers as having said, "The limitations of the services of the University Hospital to the indigent people of the state to my mind is undemocratic. The hospital should be open to rich and poor alike."

We all know that the hospitals of the University of Michigan have been pauperizing the community, not only in Michigan but in sections of Indiana and Ohio, by furnishing gratuitous medical and surgical treatment to any who applied, whether able to pay for such services or not. Even if the authorities of the University of Michigan considered that the taxpayers of Michigan were entitled to gratuitous medical and surgical services because of the taxes paid to support the institution, it is inconsistent to consider that people residing outside of Michigan, who pay no taxes to the support of the institution, should be accorded like privileges. However, the system is wholly wrong and in the end is bound to end disastrously. There is no reason why the rich or well-to-do people of Michigan should not pay for their medical and surgical services just as well as to pay for their plumbing or for any other services rendered them. If the state is going to furnish gratuitous medical and surgical services to the rich, then why not furnish them other necessities, or for that matter with automobiles or other luxuries enjoyed by the rich. We notice that most of the advocates of this pernicious form of State Medicine are safely entrenched in a soft berth for themselves, and Dr. Hugh Cabot, perhaps not being really obliged to practice medicine as a vocation, is very fortunate in being

at the head of a great University which pays him a salary that amply provides a comfortable living for him, but what about the struggling doctors, perhaps graduates of the Medical Department of the University of Michigan, who are depending upon the public for support, but who must compete with their *alma mater*, and, worst of all, an *alma mater* that donates its services to rich and poor alike? The time and money expended in securing a medical education means nothing and brings nothing unless its possessor can fall into a soft berth provided by federal, state or municipal support.

However, aside from all this discussion of the economic phase of the situation as it affects doctors, there is a far more important matter for consideration and that is the one of the limitations of the individual effort. It is quite possible that a few men occupying soft berths may continue to progress, but for the vast majority there is little initiative and in the main patients are going to fall into the hoppers of institutions that treat them in a rather impersonal and machine-like way, often-times with mediocre services. Aside from this there will be the ever present political phase of the scheme to be dealt with, and experience shows that those selected for federal, state and municipal positions are not always those who are best qualified, but those who, for one reason or another, are able to control the most influence. We have no quarrel with those who see fit to furnish free medical and surgical attention to the worthy poor, for that practice is upheld and followed by every member of the medical profession, but the scheme proposed by Dr. Hugh Cabot is unworthy of acceptance as being the best for the institution of which he is dean nor is it the best for the people of the state. For the medical profession it eventually will prove annihilation, as private practice, except in a few isolated instances, cannot exist in the face of that sort of competition.

It strikes us that Michigan has been flirting with several socialistic features, and the Medical Department of the University of Michigan long has been a thorn in the flesh of the medical profession of the state through its tendency to socialize the practice of medicine. Now comes Dr. Hugh Cabot, resplendent with the glamour of a reputation secured in the literary, aristocratic and esthetic atmosphere of Harvard University, with revolutionary and bolsheviki notions which, as dean of the Medical Department of the University of Michigan, he expects to thrust upon the people of Michigan, whether they want them or not. Perhaps a certain element among the people in Michigan will shout their approval, but what about the members of the medical profession whose throats are being cut in order to furnish greater reputation and power for men like Dr. Cabot? And what about the people who in the end will be the greatest sufferers from such an impracticable scheme? As we have said before, if we are going into this socialistic business, why not socialize everything, like they do in Russia, and get the agony of the experience over at once in order to get back to the sane conduct of affairs at an earlier date? It is as fair to put all vocations under state control as it is to put the medical profession there.

This whole question of state medicine reminds us of what we have said before, and that is that the medical profession has more to fear from members in its own ranks, men who have been placed in high positions very largely through the efforts of their fellow professional men, who are really the worst offenders in advocating and supporting some of the wild, impractical and socialistic schemes which have as their ultimate end the annihilation of private medical practice. It is time to have an accounting and separate the sheep from the goats. We may have a very high regard for Dr. Hugh Cabot's ability, but we have only condemnation and censure for him in advocating such schemes as he proposes in Michigan, and the quicker the medical profession places its stamp of disapproval upon him when he continues to advocate such socialistic schemes as the one which forms the basis of this discussion, the better it will be for the medical profession in Michigan.

CANCER CONTROL

Ninety thousand people in the United States die of cancer every year. With the present state of medical knowledge it is considered possible, by those in a position to know, to cut this death rate in half. This would mean the saving of forty-five thousand lives annually. A large proportion of these deaths are due to the fact that cancer is not recognized early. The chief reason why cancer is not usually recognized early is because the people generally are ignorant of the way cancer begins, and therefore do not consult a physician as a rule until the cancer is well advanced. Another reason why so many cancers fail of recognition early is, we regret to say, due to a lack of knowledge or appreciation on the part of some doctors of the early signs of cancer and precancerous conditions. All too often the surgeon has patients referred to him only after weeks or months of "observation", and sometimes "treatment".

The early diagnosis of cancer is not easy, but is possible in a large proportion of all cases, and in all cases save those involving internal organs. All cases of suspected cancer should be promptly subjected to a thorough examination. However, as previously indicated, the

chief reason for the high death rate from cancer lies in the ignorance of the people, and it was largely for the purpose of overcoming or reducing this ignorance that the American Society for the Control of Cancer was organized. In the dissemination of necessary knowledge to the public, this organization is using all available channels, including the lay press, clubs, moving pictures, etc., and medical societies are urged to hold meetings from time to time to which the public is invited, at which the subject of cancer is presented in a proper popular way. The society will also furnish speakers for professional meetings for the purpose of assisting in bringing the latest knowledge of malignant disease to the attention of the general practitioner. Mrs. A. J. Detzer, 910 West Wayne Street, Fort Wayne, Indiana, is the secretary of this society for Indiana. Mrs. Detzer will, upon request, supply speakers and literature for clubs and medical societies throughout the state. Women's clubs should be especially interested in this matter, for cancer is much more (about 2 to 1) frequent in women than in men. It is not perhaps generally known that among people over 40 years of age cancer causes more deaths than tuberculosis or pneumonia.

The American Society for the Control of Cancer will conduct a cancer campaign throughout the United States from October 30th to Nov. 5th. We urge every doctor and every medical organization in this state to actively support this movement. The good resulting from the campaign will depend largely upon the degree of public interest aroused, and this will depend upon the activity and interest displayed by the profession. The aim is to reach every community with the cancer message during "Cancer Week", and we urge doctors throughout the state to see to it that their particular community gets this message. A letter addressed to Mrs. A. J. Detzer, Fort Wayne, Indiana, will bring any information desired.

One death in every ten after the age of 40 in this country is due to cancer. If every doctor does his duty this death rate can be reduced one-half.

STATE MEDICINE

Henry Ford of "flivver" fame may be visionary in some things, the reputation having been gained largely through his spectacular efforts to secure peace during a dark period of the world war, but in many ways he has shown himself to be the possessor of ideas that are fundamentally sound and worthy of thoughtful consideration by the public at large. This is evidenced by his opposition to public ownership of utilities, his expression of opinion concerning the management of large commercial interests, and quite recently his opinion concerning the subject of State Medicine, which has appeared as an editorial in his international weekly, *The Dearborn Independent*. While Mr. Ford may not have been the writer of the editorial, he certainly sanctioned its appearance in his weekly, and it is so pertinent to the subject that we herewith reproduce it:

State ownership and control is perfectly sound in theory, but has proved itself wholly unsound in practice. There may be countries in the world where it is safe to trust the control of vital interests to the group of men who comprise the government; it has not always been safe in this country, as years of experience prove. The revelations of official incompetency, and not so much incompetency as dishonesty, during the recent war period, will effectually modify any theoretical appeal which the idea of state control may have.

But that there are influences in this country which are bent on bringing all the people's affairs under official scrutiny, is most apparent from the efforts now being made to create a sentiment in favor of "state medicine". This means simply: more jobs, no privacy, curtailment of freedom, the destruction of the medical profession by the discouragement of research work, and the coarsening of delicate intimacies. It means practically that what the United States Shipping Board did to the shipping situation of the country, "state medicine" would be permitted to do to the people's health.

The most astonishing feature of this propaganda is the assumption that the proposal *could* be made attractive to the American people. Most cities have city physicians now, and most counties have county physicians, and no one rests under any doubt of the quality of the services rendered. The public has had a wide experience in going to its officials for sufficient water, heat, light, school facilities and transportation service, and sufficient difficulty in getting any kind of service at all at any reasonable tax rate, to prevent its falling in love with the idea of going to its officials for a medicine when it is sick. Practically, it will not work; the genius of the American people is against it.

Between family physicians and families there is a confidential relation which rests on choice and experience. It is not official. It is not altogether professional. It partakes of the confessional in large degree, and constitutes a friendly pact based on the experience of many fights with disease and death. So well recognized is this that the family physician has become a fixed figure in our lives, and with results of undoubted good, as the records generally show.

To change all this and establish a police health station, as it were, at which citizens must apply for medical aid and await the pleasure of an official doctor who is paid anyway, and whose professional career does not depend on the confidence he is able to evoke by skilled and loyal service, is to suggest something which is so alien to our Americanism as almost to prove an alien course and an alien purpose.

With the growing predilection of a certain group for medicine and surgery, and with that group's constant predilection for securing control of the intimate sources of the people's confidence and strength, there is no doubt whatever as to what complexion "state medicine" would take if it were adopted.

These are times when more than at any previous period the American people must be on guard against *ideas* that are not American. The time has come

for the exercise of a wholesome defensive suspicion about many things that outwardly are made to appear desirable, but inwardly conceal dangers to our fundamental traditions and liberty. And we are never more justified in our suspicions of alien influences for an alien purpose than when we see attempts made to "regiment" the American people or their private affairs.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

DON'T gamble too much on the firm that is forever prating about its "quality of service". It is a good deal like tying up to a man who tells everybody how honest he is when, as a matter of fact, it is a good plan to hold on to your pocketbook when you are around him.

DR. WILLIAM R. DAVIDSON, of Evansville, the incoming president of the Indiana State Medical Association, has long been identified with the activities of the Association, and well deserves the honor that has been conferred upon him. The Association has honored itself in honoring him.

THE Christian Scientists claim that Christian Science healing is not medical practice. We admit it. In most instances it approaches fraud, and in a few instances it is criminal if used to supplant rational and tested procedures for saving life when threatened by serious diseased conditions.

ON the first of September, according to the government report, diphtheria was unusually prevalent in Indiana, the number of cases being more than twice as many as those of scarlet fever or typhoid fever. This leads us to inquire as to why the Schick test and preventive doses of toxin-antitoxin are not more generally employed.

WITH the beginning of the public schools the time has arrived for determining the susceptibility to diphtheria by employing the Schick test and immunizing children by the administration of toxin-antitoxin mixture. It would be well for physicians and public health officials to take the trouble to acquaint parents with the value of this procedure.

THE attention of readers of THE JOURNAL is called to an open location for the practice of medicine at Hemlock, Howard County, Indiana, which is left vacant by the death of Dr. L. DeWees. The town is located in a good farming community and there is no competition nearer than five miles. The office, drugs, instruments, etc., of the late Dr. DeWees are all in good condition, and definite information concerning the practice may be secured by addressing Mrs. L. DeWees, Hemlock, Indiana.

THE Indianapolis Session of the Indiana State Medical Association may be counted as one of the best ever held. There was an attendance of between five and six hundred. The papers and discussions were better than last year, and the social features were all that could be desired. The occasion was more interesting as a result of the visit of Surgeon General Ireland, a native of Indiana, who delivered the principal address at the banquet. Dr. William R. Davidson, of Evansville, was the unanimously chosen president for the ensuing year, and Muncie will be the place for the 1922 session.

MEMBERS of the medical profession can show in no better way their appreciation of any efforts on the part of the lay publications to uphold and advance scientific medicine than by subscribing to the *Woman's Home Companion* which recently has been boycotted by the antivivisectionists because of its stand in favor of animal experimentation when properly regulated. It may be possible that the *Woman's Home Companion* offers little of interest to the average doctor, yet he can place it upon his reception room table where it probably will prove interesting reading to the feminine members of his clientele.

THE osteopaths are doing a lot of newspaper advertising in an endeavor to show the public what they can accomplish by practicing their peculiar ideas. The latest thing is a brochure on the osteopathic treatment of eye, ear, nose and throat diseases. Among interesting claims put forth are those relative to the osteopathic cure of enlarged tonsils, adenoid tissue in the nasopharynx, hay fever, deafness, cross eyes, running ears, and some other affections that we know to be successfully relieved only by the application of surgery or some treatment aside from mechanical manipulations. However, it is a safe bet that the newspaper advertising will bring a lot of suckers to the net.

THE Riley Memorial Children's Hospital, to be erected in Indianapolis, is a most worthy enterprise and should have the support of the medical profession. At the Indianapolis session the Indiana State Medical Association offered its encouragement and support to the enterprise with the distinct understanding that the hospital is for the *indigent* children of the State of Indiana. We are under the impression that the addition of the word *indigent* to the endorsement of the project is thoroughly justified in this age when uplifters are offering all kinds of schemes for pauperizing the community by furnishing gratuitous medical and surgical attention to many who are not only able to pay for it but should do so.

STUDIES made by various observers definitely show that from one to three percent of all persons affected with typhoid fever become chronic typhoid carriers. These constitute a serious menace to public health and constantly threaten epidemics. To obviate the overlooking of carriers, the New York City Board of Health requires that, in addition to the two negative stools which are necessary before a case is discharged, every terminated case of typhoid fever shall be required to submit two additional stool specimens two months after termination of the case. It is thought that this additional safeguard eventually will bring to the notice of the Board of Health cases in which the discharge of typhoid bacilli from the intestines is intermittent. The plan adopted in New York City may with profit be adopted in other cities and towns throughout the country.

IT is no idle dream to look forward a few years when the medical profession will be socialized, unless something is done to stem the tide that insidiously is working in that direction. Already various socialistic and paternalistic schemes for control and supervision of the activities of the medical profession have been proposed, and in some states scarcely missed being put into operation, but the rank and file of the medical profession slumbers on content to say "why make a mountain out of a mole hill?" or "why cry 'wolf' when there is no animal in sight?" Our own idea is that it will take more than a charge of dynamite to awaken the medical profession from the lethargy it now seemingly enjoys, but the trouble of the awakening will be that it will put the profession into another sleep that will be deeper but far more troubled than the one that is being enjoyed at the present time.

OUR medical and surgical books with their illogical and ignorant teachings are now obsolete, for lo and behold, the chiropractors have discovered new theories as to the cause of disease. A leading chiropractor emits the following: "Goitre is caused by subluxations of the vertemeres, which produce pressure upon the nerves emitting from the adjacent foramina and brings about a pathological condition in which the function of expansion (cell growth, or cell multiplication) is affected; there being an excess of development of the cells to what is needed for the normal secretion of the thyroid fluid. That is, the new cells which are brought forward to replace the old, worn out or exhausted cells are being brought forth too rapidly, or before they are really needed."

"Just as clear as mud," and just as effective as antiphlogistine on the broken leg of a wooden Indian!

THE members of the medical profession, for the first time in their lives, are beginning to realize the necessity of being on guard to prevent the acceptance of various schemes proposed ostensibly for the benefit of the public good but in reality offering a means of socializing the practice of medicine. We have been lending our support to public health work of every description, and very justly so as long as the public health work has been conducted along the lines followed in years past. However, at the present moment there is a tendency on the part of many of the public health officials to so broaden the field of public health work as to make serious inroads into private medical practices and trample upon the toes of the doctors who depend upon their professional work for a living. In fact it was demonstrated at the Boston session of the A. M. A. that what we had most to fear in much of the so-called uplift work that is detrimental to the medical profession at large is the attitude of public health officials. They stood shoulder to shoulder for some actions on the part of the A. M. A. that would be not only economically detrimental to the medical profession at large, but in many instances would prove positively vicious. By all means let us be on our guard as to whom shall represent us in the House of Delegates at the A. M. A. sessions and who are to serve as officers of the parent organization. We have had quite enough of the Lambert stripe and satellites.

DR. GEORGE F. EDENHARTER, superintendent of the Central Indiana Hospital for the Insane, located at Indianapolis, announces the twenty-second annual course of clinical lectures in psycho-pathology and psychiatry, neurology and neuropathology. Dr. Max Bahr has charge of the course in psycho-pathology which is to be given during the first semester, from September 17 to January 14, and represents a series of

lectures with clinical demonstrations on the psychic elements and their derangements.

The instructors in the course in psychiatry, neurology and neuropathology are Drs. Max Bahr, Charles F. Neu and Charles D. Humes. This course is to be held during the second semester, from February 7 to May 23, and consists of the presentation and demonstration of pathologic specimens which show the pathology in the type of cases which are presented in the lectures following the demonstration. There also will be clinical conferences in the presentation of cases not scheduled by the regular lecture hour.

The hospital, with an enrollment of over fifteen hundred patients, a separate hospital for "sick insane" and a large and fully equipped pathologic laboratory with amphitheater for lectures and clinics, furnishes appropriate and abundant material for research and investigation and also affords an excellent opportunity for teaching the Science of Mental and Nervous Diseases, including their diagnosis, treatment and management. The lectures are free to practitioners and students of medicine. Further particulars may be secured by writing Dr. Geo. F. Edenharter, Indiana Central Hospital for Insane, Indianapolis, Indiana.

As an evidence of how easily the clergy is duped we have before us the advertising matter of two Indianapolis "cancer specialists" containing photographs and flattering endorsements from a number of members of the clergy. Aside from the fact that ministers of the gospel in general always have helped the progress of quackery and the sale of the most notorious humbugs in the line of proprietary medicines, a reason for the endorsement of this Indianapolis Cancer Hospital is found in a certificate which distinctly states "If you personally interest yourself in sending us one patient whom we accept as a patient at our Hospital we will immediately mail you twenty-five dollars for your trouble". On the reverse side of the certificate, preceding the line for the signature of the minister, is the following statement: "My name is not to be mentioned. This is strictly confidential." As a further inducement for the referring of patients by members of the clergy another circular is included which says that "a high grade knife will be sent, absolutely free, to a selected list of ministers who will give us the names of one or more persons who, to their knowledge, are now afflicted with cancer, lupus, or tumor. This information will be regarded as confidential and your name will not be mentioned." Among the ministers who are endorsing this quackery we find one Indiana man, advertised as Reverend F. M. Huckleberry (a fruity sounding name but a "nutty" possessor), of Franklin, Indiana. The advertising matter states that in the treatment of cancer "a liquid laboratory product has been developed which is injected directly into the cancer or tumor". In order to show that victims must go to the fountain head for their treatment, the following statement is made: "We do not sell this product to anyone. (We have no agents.) Physicians or anyone would have to learn the technique of the injection treatment before giving it to patients and rather than have it misused, we allow it to be administered only under our personal supervision." Members of the clergy who endorse this kind of quackery, and especially those who accept the commission offered for referring victims, should be driven out of the churches with which they are connected. There is room in the world for intelligent, conscientious and honest ministers of the gospel, but imposters and hypocrites should be thrown out.

DEATHS

JAMES A. STAFFORD, M.D., aged 81 years, died at his home in Newcastle, September 12, 1921, as a result of a stroke of apoplexy. Dr. Stafford graduated from the Physio Medical Institute of Cincinnati in 1867.

GEORGE W. KIRKPATRICK, M.D., of Lafayette, Indiana, died at his home September 22, at the age of eighty-six years. Dr. Kirkpatrick had retired from active practice nearly fifteen years ago and was the oldest physician in Tippecanoe County.

JOHN F. CULLY, M.D., died at his home in Bainbridge as a result of apoplexy. Dr. Cully was a graduate of the Rush Medical College, Chicago, and was a member of the Putnam County Medical Society and the Indiana State Medical Association.

S. L. ENSMINGER, M.D., aged seventy-seven years, died at his home in Crawfordsville, September 25, 1921. Dr. Ensminger graduated from the Miami Medical College, Cincinnati, in 1874 and was a member of the Montgomery County Medical Society and the Indiana State Medical Association.

A. J. KESLER, M.D., of Fort Wayne, died September 14 as the result of a hemorrhage. Dr. Kesler had been coroner of Allen County and was a member of the city board of health. Dr. Kesler graduated from the Fort Wayne College of Medicine in 1886 and was a member of the Allen County Medical Society and the Indiana State Medical Association.

HENRY H. THOMPSON, M.D., of Noblesville, died of double pneumonia at his home, September 21, 1921, at the age of forty-four years. Dr. Thompson was a graduate of the Washington University Medical School, St. Louis, and was a member of the Hamilton County Medical Society, the Indiana State Medical Association and the American Medical Association.

HARLEY H. SUTTON, M.D., of Aurora, died at his home, September 1, at the age of sixty-nine years. Dr. Sutton graduated from the Jefferson Medical College of Philadelphia in 1877. For many years he served as president of the Dearborn County Society for the Prevention of Tuberculosis. Dr. Sutton was a member of the Dearborn County Medical Society, the Indiana State Medical Association and the American Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in *The Journal of the Indiana State Medical Association*. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

DR. A. M. KIRKPATRICK, of Columbus, Indiana, recently lost a tube of radium valued at $1,200.00.

DR. A. M. SULLIVAN and family, who have been in New York since last April, returned to South Bend October 1st.

DR. S. D. BEAVERS and son, Dr. Ben Beavers, have formed a partnership for the practice of medicine at Decatur, Indiana.

DUE to the general reduction of prices on everything the physicians of Gary have reduced their call charges to two dollars.

DR. G. L. MCNEAL, of Kokomo, has returned to his office for practice after an absence of nearly three months due to illness.

THE Reid Memorial Hospital of Richmond, Indiana, has received a bequest of $30,000.00 through the will of Mrs. Helen Dongan.

DR. and MRS. A. C. CHENOWETH have moved from Wabash to Andrews, where Dr. Chenoweth has taken up the practice of medicine.

THE Methodist Episcopal Hospital and Deaconess Home, of Indianapolis, is the recipient of $6,000.00 for the endowment of a room, by the will of Fidelia Anderson.

DR. ROBERT L. MCCLURE, of Gosport, Indiana, and Miss Lorena J. Eaton, of Princeton, Indiana, were married at Franklin, August 22, 1921.

THE Grant County Medical Society held a meeting at Van Buren September 20, 1921. The principal paper was presented by Dr. Fair, of Muncie.

DR. NELSON H. YOUNG, of Toledo, has been appointed senior physician at the National Sanatorium for Veterans of the World War at Marion, Indiana.

DR. H. S. HATCH, superintendent of the Sunnyside Sanitorium, Indianapolis, and Miss Violet Wilmetta Brewer, of Southport, were married August 5, 1921.

DR. J. C. BAXTER, of Auburn, has been appointed county physician of DeKalb County. His duties are to treat the patients at the county infirmary and county jail.

DR. W. W. HARRIS, of Ellettsville, Indiana, who was in charge of the federal war risk board until its recent abolishment, will reopen his office on North Washington street.

DR. T. SCOTT SCHILDT, of Bremen, Indiana, will remove to Princeton, where he has purchased the property, equipment and practice of an old physician, for the practice of medicine.

DR. E. D. CLARK, of Indianapolis, who was operated for gall stones at the Lakeside Hospital, Cleveland, the latter part of September, is reported as making a very satisfactory recovery.

DR. and MRS. R. S. GALBREATH will leave Huntington the first of November to spend the winter in New York, where Dr. Galbreath will take a course in surgery. They plan to return to Huntington in the spring.

DR. L. L. BULLEIT, of Palmyra, is taking a six months' postgraduate course in Chicago after which he will locate and continue his practice. His present practice will be taken up by Dr. Robertson, of Campbellsburg.

THE Washington County Medical Society held its regular meeting at Salem, Wednesday evening, September 7. A paper on obstetrics was presented by Dr. W. L. Green and several reports on cases of typhoid fever were given.

DR. JOHN H. WILLIAMS and family, of Cowan, Indiana, have recently returned from a motor tour of the East, having covered the whole trip of 3,000 miles with a camping trailer, and sleeping in the open during the whole trip.

THE regular monthly meeting of the Anderson Academy was addressed by Dr. D. W. Crile, of the Augustine Hospital in Chicago, on the subject of "Fractures". Drs. T. E. Eckhart, of Marion, and S. A. Marshall, of Kokomo, also discussed this subject.

DR. C. W. HOWARD, of Crawfordsville, and Miss LaVerna Schultz, of Newtown, were married August 27, 1921. After a short wedding trip they will be at home in Crawfordsville where Dr. Howard specializes in the practice of the eye and ear.

THE U. S. Public Health Service has arranged to hold a series of twenty-four institutes at various population centers throughout the country. No tuition is to be charged for these institutes, one of which will be held at Indianapolis from February 13 to 18.

ANNOUNCEMENT has been made of the establishment of a new firm in Franklin, Indiana, by the name of Records & Records, the members of which are Drs. John N. Records and A. W. Records. They will occupy the offices left vacant by the late Dr. L. L. Whitesides.

DRS. C. R. BIRD, D. E. DOUGLAS and W. E. THOMAS have been appointed surgeons to take the place of Dr. Paul Tindall on the Big Four Railroad. While there has been only one surgeon doing this work, it was decided to divide the work among three.

ACCORDING to plans completed by Secretary Hoover several hundred nurses will be recruited in the United States for the purpose of aiding in giving American relief to Russia's needy children. It is expected that, for the most part, these will be selected from the number who saw service in France.

THE Agricultural Department of Purdue University has furnished valuable ideas and instructions to the State of Indiana concerning bovine tuberculosis. Already thirteen counties of the state have launched campaigns against that disease. It is the plan to eliminate all tuberculosis in beef and dairy cattle.

DR. KATHRYN M. WHITTEN, of Fort Wayne, and Dr. A. H. Unthank, a dentist of Marion, were married August 24, 1921, at their home which they recently purchased in Fort Wayne. Dr. and Mrs. Unthank will continue their practices in their combined offices at 343 West Wayne street, Fort Wayne.

THE Whitley County Council has appropriated a thousand dollars for the purpose of building two portable cottages for the care of tuberculosis patients and to aid in carrying on the nurses' services. A plan is also under consideration for paying for the upkeep of five beds at the Irene Byron Hospital at Fort Wayne.

THE Tri-State District Medical Society has issued an invitation to the physicians of Indiana to attend its annual assembly which is to be held at Milwaukee, Wisconsin, November 14th, 15th, 16th and 17th. There will be addresses by many well known doctors. Dr. Charles P. Emerson, of Indianapolis, will present a paper on "The Treatment of Chronic Nephritis".

THE Indiana State Nurses' Association, together with the hospitals and Red Cross, are developing a movement to stimulate interest in the nursing profession. The state will be divided into districts and a very complete program will be carried out in each community. The number of trained nurses in this country has been greatly decreased and it is hoped that this campaign will help to bring this number back to its full strength.

A POSTGRADUATE course in anatomical and operative surgery on the head and neck will be offered by the Indiana University School of Medicine at Indianapolis, beginning October 24, 1921. The course will be conducted by Dr. John F. Barnhill, Professor of Rhinology, Otology and Laryngology. Further particulars regarding this course may be obtained from the Registrar, Indiana University School of Medicine, Indianapolis, Indiana.

THE members of the Indianapolis Board of Park Commissioners have announced that ground lying between the Robert W. Long Hospital and the City Hospital, facing the proposed site of the Riley Memorial Hospital for Children, will be acquired by the park board for use as a convalescent park. It has been pointed out that establishment of the three hospitals in close proximity will result in economical operation through combined facilities.

THE American Hospital Association held its annual meeting at the West Baden Springs Hotel, West Baden, Indiana, September 12-16. Papers were presented by Dr. Haven Emerson on the Bureau of War Risk Insurance; Dr. Malcolm T. MacEachern, on "What Constitutes Good Service to the Public"; Charles S. Woods, on "The Development of Good Professional Work in the Hospital"; Franklin Martin, on "The Work with Hospitals by the American College of Surgeons"; and a paper by Dr. Franklin R. Nuzum on "A Method for Increasing Medical Efficiency Within the Hospital". The president for the next year is Dr. George O'Hanlon, superintendent of Bellevue Hospital, New York.

THE memorial to be erected to Dr. John B. Murphy, noted doctor and teacher, is to be in the form of a beautiful building which will be dedicated to the service of the American College of Surgeons of which Dr. Murphy was a founder. Mrs. John B. Murphy recently passed away, leaving $100,000.00 in support of the memorial conditional upon the entire $500,000.00 being raised and the proposed building begun within a limited time. Therefore, special efforts are being put forth to obtain the remaining $300,000.00, $200,000.00 already having been received. Doctors are especially urged to contribute to this worthy memorial and all contributions will be welcomed. Address Dr. John B. Murphy Memorial Association, Room 1314, 30 North Michigan Avenue, Chicago.

THE Eleventh District Medical Association will hold its annual meeting at the Marion National Sanatorium, Marion, Indiana, Oct. 20, 1921. The following program will be carried out:

From 11 A. M. to 12:30 P. M.—Clinics at the Marion National Sanatorium, by Dr. Wm. MacLake, Medical Director and Superintendent.

2:30 P. M.—Inspection of hospitals and laboratories under guidance of Sanatorium staff. Business session and Scientific Program.

The following papers will be presented: "Ectopic Pregnancy," by Dr. C. H. Good, Huntington; discussants—Drs. G. G. Eckhart and Wallace Grayston; "The Management of Nephritis," by Dr. Wm. A. Jenkins, Louisville, Ky.; "The Place of the Public Nurse," by Dr. James Wilson, Wabash; discussants—Drs. J. H. Reed and E. O. Daniels.

AN Institute on the Nutrition Problems of Children will be held at Indianapolis for two weeks, beginning October 24, 1921. It will be conducted by Dr. William R. P. Emerson, of Boston, and will be under the auspices of the Marion County Tuberculosis Association. The institute will be open to all teachers, nurses, dietitians, social workers and other interested people.

The entire time of the students will be taken up by the institute for the two weeks, and lectures will cover the various phases of nutritional work. Actual demonstrations will be presented in the nutrition classes which will be organized in the Indianapolis schools before the institute begins, and these classes will be continued throughout the school year. Special lectures will be arranged for late in the afternoon or evening with the cooperation of Parent-Teacher Associations, Women's Clubs, etc. There will be no admission fee to these lectures. The total cost of the Institute, including tuition fee, will be twenty-five dollars. A reduced fee of ten dollars is made to people of Indianapolis and Marion County.

Further information may be secured from the office of the Marion County Tuberculosis Association, 1138 Pythian Building, Indianapolis, Indiana.

DURING September the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies:

The Abbott Laboratories: Procaine-Adrenalin Hypodermic Tablets No. 2.

Dry Milk Co.: Protolac.

Hynson, Westcott & Dunning: Tablets of Benzyl Succinate—H. W. and D.

Intra Products Co.: Ampules Ven Sterile Solution Mercury Oxycyanide 0.008 Gm. Ampules Ven Sterile Solution Mercury Oxycyanide 0.016 Gm.

Lederle Antitoxin Laboratories: Acne Combined Vaccine.

Mead, Johnson & Co.: Casec.

N. Y. Intravenous Laboratory: Loeser's Intravenous Solution of Mercury Oxycyanide.

Seydel Mfg. Co.: Benzyl Succinate—Seydel.

Nonproprietary Articles: Benzyl Succinate. Calcium Caseinate.

THE Indiana University School of Medicine announces a postgraduate course in blood chemistry, methods of testing kidney function, acidosis, and basal metabolism, to occupy a period of about ten evenings, for physicians of Indianapolis and the vicinity. The laboratory of the Medical School building will be open for this purpose on Thursday evenings from 7:00 till 10:00 o'clock throughout the coming year, commencing October 27. The principal subjects to

be covered will be determination of urea in the blood, relation between urea excretion and blood urea concentration as expressed by Ambard and others, determination of creatinine, uric acid, and sugar in the blood, detection of acidosis and determination of alkaline reserve, determination of alveolar carbon dioxide and measurement of basal metabolism. Short explanatory lectures will be given at intervals, but the work will be chiefly of a practical character, provision being made for each member of the class to carry out analyses himself. The course is to be conducted by B. B. Turner, professor of pharmacology and biochemistry, assisted by Hobart Rogers, associate.

THE National Board of Medical Examiners has just completed the first five years' work and with it the trial period of its usefulness. The principle which this Board has stood for, namely, the establishment of a thorough test of fitness to practice medicine which might be safely accepted throughout this country and abroad, has been widely accepted. Since this Board was organized by Dr. W. L. Rodman, in 1915, eleven examinations have been held. These examinations have been conducted on the plan of holding at one sitting a written, practical and clinical test for candidates with certain qualifications, namely, a four-year high-school course, two years of college work, including one year of Physics, Chemistry, and Biology, graduation from a Class *A* Medical School and one year's internship in an acceptable hospital. These examinations have covered all the subjects of the medical school curriculum and have been conducted by members of the Board with members of the profession resident in the place of examination appointed to help them. Such examinations have been held in Washington, Philadelphia, New York City, Boston, Chicago, St. Louis, Rochester (Minnesota) and Minneapolis. During the war a combined examination was held at Fort Oglethorpe and Fort Riley. There have been 325 candidates examined, of whom 269 have passed and been granted certificates.

Starting with the endorsement of the Council on Medical Education of the American Medical Association, American Medical College Association and various sectional Medical Societies, the recognition of the Army, Navy and Public Health Service Medical Corps of the United States and certain State Boards of Medical Examiners, the certificate is now recognized. Also by twenty states as follows: Alabama, Arizona, Colorado, Delaware, Florida, Georgia, Idaho, Iowa, Kentucky, Maryland, Minnesota, Nebraska, New Hampshire, New Jersey, North Carolina, North Dakota, Pennsylvania, Rhode Island, Vermont, and Virginia, the Conjoint Board of England, the Triple Qualification Board of Scotland, the American College of Surgeons and the Mayo Foundation of the University of Minnesota.

There has been such a wide-spread demand for an opportunity to secure this certificate by examination that the Board has now adopted and will put into effect at once, the following plan: Part I, to consist of a written examination in the six fundamental medical sciences: Anatomy, including histology and embryology; Physiology; Physiological Chemistry; General Pathology; Bacteriology; *Materia Medica* and Pharmacology. Part II, to consist of a written examination in the four following subjects: Medicine, including pediatrics, neuropsychiatry, and therapeutics; Surgery, including applied anatomy, surgical pathology and surgical specialties; Obstetrics and Gynecology; Public Health, including hygiene and medical jurisprudence. Part III, to consist of a practical examination in each of the following four subjects: Clinical Medicine, including medical pathology, applied physiology, clinical chemistry, clinical microscopy and dermatology; Clinical Surgery, including applied anatomy, surgical pathology, operative surgery, and the surgical specialties or the diseases of the eye, ear, nose and throat; Obstetrics and Gynecology; Public Health, including sanitary bacteriology and the communicable diseases.

Parts I and II will be conducted as written examinations in Class *A* Medical Schools and Part III will be entirely practical and clinical. In order to facilitate the carrying out of Part III subsidiary boards will be appointed in the following cities: Boston, New York, Philadelphia, Minneapolis, Iowa City, San Francisco, Denver, New Orleans, Baltimore, Galveston, Cleveland, St. Louis, Chicago, Washington, D. C., and Nashville, and these boards will function under the direction of the National Board. The fee of $25.00 for the first part, $25.00 for the second part and $50.00 for the third part will be charged. In order to help the Board the Carnegie Foundation has appropriated $100,000 over a period of five years.

At the annual meeting, held June 13th of this year in Boston, the following officers were elected: M. W. Ireland, Surgeon General, President; J. S. Rodman, M.D., Secretary-Treasurer; E. S. Elwood, Managing Director.

Mr. Elwood will personally visit all Class *A* Schools during the college year to further explain the examination, etc., to those interested. Further information may be had from the Secretary-Treasurer, Medical Arts Building, Philadelphia.

CORRESPONDENCE

JOHNS HOPKINS ON SURGICAL FEES

Cincinnati, Ohio, Sept. 6, 1921.

Editor of THE JOURNAL:

In the August issue of "The Journal of the Indiana State Medical Association," under Editorials on page 271, I found a short article entitled "Johns Hopkins Decision Concerning Surgical Fees".

In commenting on this article I beg to state that I agree with every word of it and am sure every other sane thinking physician does likewise. I only wish that other medical journals had the same courage to go after the "big fish" when the occasion demands.

I always have enjoyed reading your editorials and admire your courage in saying just what you think, and hope that you will continue along the same lines.

Sincerely yours,
C. J. BROEMAN, M.D

CHRISTIAN SCIENCE

Chicago, Ill., Sept. 3, 1921.

Editor of THE JOURNAL:

I have just finished reading your editorial on "Christian Science" and hasten to express my appreciation of your attitude toward this pseudo-religious medical fake. There are some near-sages who assert that deceit thrives on opposition. Any successful pickpocket is more than willing to be let alone, and the "Christian Science" pickpocket is no exception. Pitiless publicity is all that is required to counteract the mysterious fanaticism of the Eddyites. It is useless to expect the lay press to take any sensible stand in the matter, as members of this cult have hounded the newspapers into subjection. For a number of years I have been convinced that this baby-killing cult should be given the benefit of the spotlight. Every case of death due to neglect should be thoroughly aired; and where possible have it generally known who is responsible for the untimely death.

I trust your able excoriation of the praying pickpocketeers will be emulated.

Sincerely yours,
CHAS. E. HUMISTON (M.D.)
(President Illinois State Medical Society)

PRAISE FOR THE JOURNAL

Brazil, Indiana, Sept. 2, 1921.

Editor of THE JOURNAL:

As a member of the Indiana State Medical Association, I wish to express hearty appreciation of your work in editing THE JOURNAL. This year's issues have been the best yet, and while the scientific papers contributed by members have been of a high order of merit, your own editorial notes and leaders also have shown a sustained excellence and timeliness.

The series of articles by Dr. Frank B. Wynn is a most praiseworthy one, and quite remarkable for its fearless frankness in dealing with some more or less common shortcomings of members of our own profession. Your leading editorial this month on Christian Science is very much to the point, and the sentiments there expressed should be widely distributed among both profession and laity.

However, one of your notes intimating that the Indiana State Board of Health is about to be reorganized, leaving out the present Regulars and their influence, rather mystified some of us as to its possible hidden meaning. Of course we know that just lately there have been rumors as to some members and employees receiving double pay in some way, and the insinuation that probably city and county health officers were getting a wartime graft from Federal sources, etc. Local health men WERE asked to do a lot of extra work and the demand still continues, but all the time with no EXTRA REMUNERATION WHATEVER. I only hope that in reorganizing the State Board, if found necessary, that men of high ideals and strict integrity as well as high professional standing can be induced to take the management.

Very truly yours,
GEORGE W. FINLEY, M.D.,
County Health Commissioner.

APPROVAL FROM CALIFORNIA

San Francisco, Cal., Sept. 27, 1921.

Editor of THE JOURNAL:

I have received the extra copies of your Journal which we requested, and wish to thank you for the courtesy extended.

We have been particularly interested in the editorials. It is a pleasure to note that you are up and doing in your part of the world. We are trying to do the same.

Sincerely yours,
W. E MUSGRAVE,
Secretary, California State Medical Society.

THE TRUTH ABOUT MEDICINES

NEW AND NONOFFICIAL REMEDIES

BEEBE PROTEIN MILK.—EDWEISS MILCH OF FINKELSTEIN.—A modified milk preparation having a relatively low content of carbohydrate and fat and a relatively high protein content. Each 100 Gm. contains approximately solids 10.2 Gm., carbohydrate 2.5 Gm., protein (casein) 5.3 Gm., fat 1.6 Gm., and ash 0.8 Gm. The acidity is stated on each package. The high protein content of protein milk is claimed to act as a preventive of fermentation and to serve as a medium in which a change in the intestinal flora takes place. Protein milk is said to be especially indicated in gastro-intestinal disorders of infants, accompanied by fermentation and diarrhea. Beebe Laboratories, Inc., St. Paul, Minn.

BEEBE MODIFIED BUTTERMILK.—Buttermilk with Flour.—Buttermilk modified formula of Langstein and Meyer.—Buttermilk containing flour partially dextrinized by heat.—Each 100 Gm. contains approximately total solids 9.7 Gm., carbohydrate 4.7 Gm., protein 3.3 Gm., fat 0.6 Gm., and ash 1.2 Gm. The acidity is stated on each package. Beebe Modified Buttermilk is offered as a means of combating intestinal fermentation by modifying the intestinal flora. Since it contains several forms of carbohydrates which have different periods of digestion, it is believed to afford an opportunity of assimilation without overtaxing the digestive powers. It is stated to be indicated in digestive disturbances of children and adults characterized by milk dyspepsia, fat intolerance, eczema and vomiting. Beebe Laboratories, Inc., St. Paul, Minn.

MERCURIC OXYCYANIDE.—For a description see New and Nonofficial Remedies 1921, p. 194. Mercuric Oxycyanide has been proposed as a substitute for mercuric chloride. Its antiseptic power is said to be greater and it is claimed to be less irritating than mercuric chloride because it does not act on albumin to the same extent. Representative syphilographers differ as to the use of mercuric oxycyanide intravenously. Some believe that its use should be limited to hospitals; others that it has no advantage over other and safer methods of administering mercury, while others consider it safe and valuable. But all are in accord that its safe use requires experience. Mercuric oxycyanide may be administered subcutaneously, intramuscularly or intravenously in the same doses as mercuric chloride.

LOESER'S INTRAVENOUS SOLUTION OF MERCURY OXYCYANIDE.—Each ampule contains 5 Cc. of solution, representing 0.008 Gm. mercuric oxycyanide, N. N. R. New York Intravenous Laboratory, New York.

AMPULES VEN STERILE SOLUTION MERCURY OXYCYANIDE, 0.008 GM.—Each ampule contains 5 Cc. solution, representing 0.008 Gm. mercuric oxycyanide, N. N. R. Intra Products Co., Denver, Colo.

AMPULES VEN STERILE SOLUTION MERCURY OXYCYANIDE, 0.016 GM.—Each ampule contains 5 Cc. solution, representing 0.016 Gm. mercuric oxycyanide, N. N. R. Intra Products Co., Denver, Colo. (*Jour. A. M. A.*, Sept. 10, 1921, p. 863).

CALCIUM CASEINATE. — Calcii Caseinas. — Casein from cow's milk, rendered partially soluble by combination with calcium and containing not less than 1 percent of calcium. The diarrheal diseases of infancy are now generally treated by dietetic measures. A useful food may be made from the curd of milk and diluted buttermilk, the resultant mixture containing a moderate amount of fat, a small amount of sugar and a large amount of protein (casein) and salts, particularly salts of calcium. A mixture of calcium caseinate and milk is also used. For children, calcium caseinate is mixed with milk and water or milk and gruel in the proportion of 10 Gm. calcium caseinate and one pint of the liquid and the mixture boiled. Calcium caseinate is a yellowish powder, free from rancid or sour odor. With warm water it forms a turbid suspension. Calcium caseinate must not contain more than 10 percent of moisture, nor more than 2.5 percent of fat and not less than 14 percent of nitrogen.

CASEC.—A brand of calcium caseinate, N. N. R. Mead, Johnson & Co., Evansville, Ind.

BENZYL SUCCINATE.—Benzylis Succinas.—The dibenzyl ester of succinic acid. Benzyl succinate lowers the tone of unstriped muscle, its action being similar to benzyl benzoate in this respect. It is superior to benzyl benzoate in being less irritating, less nauseating and in containing a greater proportion of benzyl radicle. Its use has been suggested as a renal, biliary, uterine and intestinal colic, excessive intestinal peristalsis, dysmennorrhea, hiccough and other spasms of unstriped muscle. Its clinical use is still in the experimental stage. The dose is 0.3 to 1.0 Gm. Benzyl succinate is a crystalline, odorless and almost tasteless powder. It is almost soluble in water, but soluble in alcohol.

TABLETS OF BENZYL SUCCINATE-H. W. and D.—Each contains benzyl succinate, N. N. R., 5 grains. Hynson, Westcott & Dunning, Baltimore.—(*Jour. A. M. A.*, Sept. 25, 1921, p. 1023).

PROPAGANDA FOR REFORM

THYROID IN OBESITY.—J. H. Means carried out studies which show that the basal metabolism is normal in cases of simple obesity. The wide-spread treatment of obesity by the administration of thyroid preparations is a device for raising metabolism to an abnormal level. The treatment of simple obesity by producing a state of hyperthyroidism has recently been designated as pernicious by Means. Simple obesity can now readily be differentiated from the obesity due to endocrine disorders by determination of the basal metabolism. If this is normal, weight reduction should not be attempted by the use of thyroid.—(*Jour. A. M. A.*, Sept. 3, 1921, p. 792).

MAGHEE'S EPILEPSY TREATMENT.—This is sold on the mail-order plan by Thomas G. Maghee, M.D., Lander, Wyo. The product is advertised with the claim that it stops all seizures from the first day of its use. A five dollar size package containing 40 capsules was submitted to the A. M. A. Chemical Laboratory for analysis. The examination indicated that each capsule contained about 1 grain phenobarbital (luminal), ½ grain charcoal and a little bismuth subnitrate. There is no rational excuse for the sale of phenobarbital (luminal) in a secret mixture sold for the self treatment of epilepsy.—(*Jour. A. M. A.*, Sept. 24, 1921, p. 1037).

THE EXPENSIVE "POOR MAN'S MEDICINE".—A favorite argument of the nostrum exploiters, advanced when threatened with restrictive legislation or taxation, is that "patent medicines" are the poor man's medicine. Never had a pretension a flimsier basis of fact. The purchaser who buys a bottle of Dr. Quack's Quick Cure does not realize that about 75 cents of his dollar has been expended by Dr. Quack in an effort to convince him that he is suffering from something for which "Quick Cure" is a sure-shot remedy. The abolition of "patent medicine" advertising would do much to abolish the making of hypochondriacs by suggestion and would result in a great decrease in all drug taking. In addition, if John Doe purchased a simple home remedy, he would have to pay for the cost of the medicine only and not for an expensive advertising campaign to promote its sale.—(*Jour. A. M. A.*, Sept. 10, 1921, p. 867).

DIPHTHERIA PREVENTIVE MEASURES.—It seems likely that the securing of widespread immunity is to be an important aim in the prevention of diphtheria. In this work the Schick test, whereby the existence of immunity or susceptibility to diphtheria can be determined with ease and precision, seems destined to play an important part. Thousands of tests have been applied to school children of New York. Further, in the recent test of more than 52,000 school children of New York, those who gave a positive test were injected with toxin-antitoxin mixture to secure active immunization. If the medical profession accepts the contention that the Schick test is a reliable indication of the susceptibility to diphtheria and, further, that the currently proposed methods of toxin-antitoxin injections are effective in developing a lasting immunity, a great step in progress will have been made.—(*Jour. A. M. A.*, Sept. 24, 1921, p. 1025).

A NEW SELENIUM CANCER CURE.—Medical journals have received "news items" from the "Medical News Bureau" (D. E. Woolley, manager) which announce that for the purpose of further developing methods of control and treatment of disease by the use of selenium and tellurium, the Basic Cancer Research has been organized and a laboratory established at 847 Union St., Brooklyn. Newspapers, on the other hand, have received free publicity matter from the Cosmopolitan Research Society (D. E. Woolley, secretary) according to which this society has been founded to investigate and develop methods for the treatment of cancer. It is further stated that "Dr. Frederic Klein, the eminent authority on urinology and the chemistry of cancer, has evolved a new colormetric test which is the most wonderful and valuable discovery in the diagnosis of cancer and various other diseases". Klein is the gentleman who made "Sulpho-Selene", a cancer "cure" which the Council on Pharmacy and Chemistry refused recognition some years ago. Is "Sulpho-Selene" to be resurrected?—(*Jour. A. M. A.*, Sept. 3, 1921, p. 805).

The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Mott's Compound Female Pills (Williams Manufacturing Co.), consisting essentially of aloes, ferrous sulphate and cantharides and falsely claimed to restore the menstrual flow and to be beneficial in female disorders. Job Moses, J. Clarke's Female Pills (Williams Manufacturing Co., and Eastern Drug Co.).

Strength and **Pliability** are Found in

Armour Iodized Sheep Gut Ligatures

which are made from lamb's gut selected in our abattoirs especially for surgical purposes.

The **Armour Iodized Ligatures** possess full tensile strength and their pliability prevents breakage at the knot. They are iodized to the core and are absolutely sterile. Regular lengths, sizes 00 to number 4 at $2.50 per dozen.

We also offer **Plain** and **Chromic Ligatures,** sizes 000 to number 4 regular lengths $2.50 per dozen, emergency lengths, $1.50 per dozen (nothing but the smooth side of the intestine is used in the manufacture of the Armour ligatures).

LABORATORY PRODUCTS

Suprarenalin Solution, 1:1000 is stable, uniform and free from preservatives.

Pituitary Liquid is physiologically standardized and is ready for hypodermatic use—½ c. c. ampoules for obstetrical and 1 c. c. ampoules for surgical use.

Literature upon the ARMOUR LABORATORY PRODUCTS for the medical profession only.

SAVE MONEY ON YOUR X-RAY SUPPLIES

Get Our Price List and Discounts on Quantities Before You Purchase

HUNDREDS OF DOCTORS FIND WE SAVE THEM FROM 10% TO 25% ON X-RAY LABORATORY COSTS

AMONG THE MANY ARTICLES SOLD ARE

X-RAY PLATES. Three brands in stock for quick shipment. PARAGON Brand, for finest work; UNIVERSEAL Brand, where price is important.

X-RAY FILMS. Duplitized or Double Coated—all standard sizes. X-Ograph (metal backed) dental films at new, low prices Eastman films, fast or slow emulsion.

BARIUM SULPHATE. For stomach work. Finest grade. Low price.

COOLIDGE X-RAY TUBES. 5 Styles. 10 or 30 milliamp.—Radiator (small bulb), or broad, medium or fine focus, large bulb. Lead Glass Shields for Radiator type.

DEVELOPING TANKS. 4 or 6 compartments stone, will end your dark room troubles. 5 sizes of Enameled Steel Tanks.

DENTAL FILM MOUNTS. Black or gray cardboard with celluloid window or all celluloid type, one to eleven film openings. Special list and samples on request. Price includes your name and address.

DEVELOPER CHEMICALS. Metal, Hydroquinone, Hypo, etc.

INTENSIFYING SCREENS. Patterson, TE, or celluloid-backed screens. Reduce exposure to one-fourth or less. Double screens for film. All-metal Cassettes.

LEADED GLOVES AND APRONS. (New type glove, lower priced.)

FILING ENVELOPES with printed X-Ray form. (For used plates.) Order direct or through your dealer.

THE TRIAD VIRTUES OF

Mercurochrome-220 Soluble

Which Promote Its Efficiency

POTENCY IN GERMICIDAL ACTIVITY

Laboratory tests have proved its high rank in bacteria killing power in various media.

NON-IRRITABILITY TO SENSITIVE SURFACES

Solutions of sufficient strength to be potent can be used on the most sensitive mucosa with little or no irritation.

PENETRABILITY AND FASTNESS

Its penetrating qualities increase the field of its activity. The stain fixes the germicide in this field until bactericidal action can take place.

Recommended not as a panacea, but for the intelligent use of the medical profession.

"H. W. & D." —SPECIFY— "H. W. & D."

Hynson, Westcott & Dunning

BALTIMORE

(Continued from page 370)
consisting essentially of aloes, a salt of iron and oil of peppermint, falsely claimed to be good for many painful and dangerous female disorders. Gono Capsules 761, Renol Capsules, and Gonna Specific (Grape Capsule Co.), capsules containing salol, oleoresin of cubebs, copaiba balsam, pepsin, cottonseed oil and plant extractives and falsely labeled as remedies for "Gonorrhea, Gleet and All Kidney and Bladder Troubles". Haskin's Nervine (Haskin Medicine Co.), a solution of Epsom salt, sweetened, flavored and colored, and asserted to be the great nervine and blood purifier and for the treatment of a very long list of disorders.—(*Jour. A. M. A.*, Sept. 17, 1921, p. 958).

TREATMENT OF "HAY FEVER".—Although the essential features of the etiology of "hay fever" are believed to be understood, the treatment is still largely of the hit or miss type. Preparations of mixed pollens are distributed by commercial houses and used by physicians in the hope that some ingredient will prove to be potent. Several facts seem at length to be so well established that they may serve almost as axioms in the clinic of hay fever. One of these is that although the offending pollens vary in different parts of the world as well as at different seasons, the number chiefly responsible for the attack in any single locality is comparatively small. Hence it becomes the duty of the physician to familiarize himself with the offending pollens in his locality or the locality whence his patients hail. Fortunately I. C. Walker has reported on the pollens which are responsible for "hay fever" in the New England states; G. Selfridge on those in California; K. K. Koessler for Illinois, and W. Scheppegrell for the Southern states. It is important that for each case of "hay fever" the offending pollen should be determined by skin tests and also that the treatment should be preseasonal (although treatment during the season may sometimes benefit). In extenuation of the frequent failure to relieve patients, it is to be noted that certain persons have symptoms ranging from sneezing to asthmatic attacks due to the odors of flowers that have no pollen as well as to the presence of nonspecific factors in the respired air. Obviously, pollen extracts are of no avail in such cases. —(*Jour. A. M. A.*, Sept. 3, 1921, p. 791).

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Equinox Lithia Water (Equinox Mountain Spring Co.), falsely claimed to be a natural mineral water. Antilaiteuse (Dr. N. A. Sirois), consisting essentially of Epsom salt and ground juniper berries falsely claimed to be able to cleanse and relieve the body and blood of all poisonous impurities. Madam Dean's Female Pills (Martin Rudy), consisting essentially of quinine, aloes, ferrous sulphate, hydrastis, ginger and cornstarch, falsely claimed to give relief in female disorders. Donaldson's Wonderful New Life Remedy (T. Donaldson Medicine Co.), essentially an alkaline solution containing Epsom salt, senna, plant extractives, alcohol and small amounts of volatile oils, falsely claimed to be one of the greatest kidney medicines in the world. Prescription 999 (Combination Remedy Co.), a mixture of fixed and volatile oils, including oils of sandalwood, nutmeg and copaiba, and falsely labeled as a remedy for gonorrhea or gleet. Kellogg's Sanitone Wafers (F. J. Kellogg Co.), containing salts of iron and chromium, a laxative plant extractive, red pepper and a trace of strychnine, sold under the false claim that locomotor ataxia is curable with chromium sulphate. Acme Brand Pennyroyal Pills (S. Pfeiffer Mfg. Co.), consisting of aloes and oil of pennyroyal and tansy, sold under claims usual to nostrums for the alleged cure of suppressed menstruation. Cadomene Tablets (Blackburn Products Co.), consisting essentially of zinc phosphide, strychnine and iron salts and recommended for neurasthenia, general debility, melancholy, etc. Leonardi's Injection No. 1 (S. D. Leonardi & Co., Inc.), essentially an alkaline solution of borax, camphor and berberin, and falsely claimed to be an effective remedy for gonorrhea and gleet. Dr. J. H. McLean's Sarsaparilla Compound (Dr. J. H. McLean Medicine Co.), a "blood purifier" consisting essentially of iodides, a laxative plant drug, saponin (sarsaparilla), plant extractives, salts of iron, potassium, and sodium, sugar, alcohol, and water.—(*Jour. A. M. A.*, Sept. 10, 1921, p. 879).

TREATMENT OF TUBERCULOSIS OF THE ANKLE IN AN ADULT

The prognosis of tuberculosis of the ankle in the adult with conservative treatment, according to F. J. Gaenslen and C. C. Schneider, Milwaukee (*Journal A. M. A.*, Oct. 8, 1921) is poor. In the present series no case of astragalotibial disease was treated conservatively, the only nonoperative case reported being one of the subastragalar disease. The duration of conservative treatment in the cases terminating favorably, according to the only statistics referring to adults, is four years. A six months' period of conservative treatment will probably be sufficient to determine efficiency of this form of treatment. In cases in which operation is performed early it is probably safe to say that the patient will return to work in between one and two years. Statistics show that amputation and also death from other forms of tuberculosis is far too frequent because conservative measures are persisted in for too long a period. In further reports, separation of cases into adult and childhood groups is urged.

COUNTING OF BLOOD CELLS AND BACTERIA

By substituting hen's erythrocytes, with their distinctive appearance, for human red cells as the standard suspension; by preparing them in such a way that they form a stable, unchanging standard suspension; by enumerating the standard suspension with great precision in an accurate counting chamber; by mixing standard suspension in measured proportion with the suspension to be enumerated, and counting them in the wet state, George Dreyer, Oxford, England (*Journal A. M. A.*, Oct. 8, 1921) asserts a very accurate method for the enumeration of human red cells and bacteria is achieved without sacrificing any of the rapidity of Wright's technic. The details of the procedure are given.

MacKEE X-Rays and Radium *Just Ready*

In the Treatment of Diseases of the Skin

The advent of this book was eagerly awaited not only by the specialists in Roentgenology and Dermatology but by practitioners. There is no work today comparable to it—it is unique—and to obtain the *information the physician must have to employ x-rays properly* for therapeutic purposes, this book is essential.

To a greater extent each year X-RAYS and RADIUM are being employed in the treatment of cutaneous diseases. They constitute *the most important single remedies in the armamentarium of pure dermatology.* Unfortunately they are dangerous agents in unskilled hands. Every physician who employs X-RAYS and RADIUM should have a thorough training, and should possess modern knowledge and equipment. There is today fairly exact knowledge of the nature, biological action, therapeutic effects and technic of x-rays and radium, and the physician should acquire this knowledge before attempting to employ these agents for the relief of human ailments. This work correlates the specialized training of the dermatologist and roentgenologist, and includes the essential elements of physics and biology.

There has been a persistent call *for the right book* on this subject and we believe that Dr. MacKee, out of his long clinical experience, has written it. In addition to the sections on the various cutaneous affections the chapters on Apparatus, Tubes, Measuring *X*-ray Dosage, Practical Roentgen-ray Technic (Unfiltered), Technic for the Beginner, Filtered Roentgen-ray Technic, Radium Technic, Clinical Effects of Radium and Roentgen Rays on the Skin, Action of *X*-rays and Radium on Pathological Tissue and General Therapeutic Considerations will be found most practical and instructive, while the value of the chapter on The Medico-legal Relations of Roentgen Therapy and Radium Therapy will be appreciated by all.

By GEORGE MILLER MacKEE, M.D., Assistant Professor of Dermatology and Syphilology, College of Physicians and Surgeons, Columbia University; Consulting Dermatologist and Syphilologist, St. Vincent's Hospital, New York, etc. Octavo, 602 pages with 250 engravings and 22 charts. *Cloth, $9.00.*

MEDICINE AND STATE CONTROL

DR. DAVID ROSS,
INDIANAPOLIS, INDIANA

Probably no question interests the medical profession more than the proper relation of the State to the practice of medicine. Certainly the powers that grant privileges should retain the right to say what shall be the conditions under which these privileges are used. The present status of the State to the education of physicians and the practice of medicine in all of its phases has been a slow evolution in which certain fundamental principles have been established. It is a long cry from the early standards of medical practice, not only in Indiana but in all the states, to the standard of today, and we may rightly claim that we have one standard throughout our country because of the uniform requirements in all states. State control of the education of medical students, and a standard agreed upon by members of the several colleges, make this possible and certain because the requirements of the men who practice the healing art not only may but must be the same no matter where the art is practiced. Education is eminently one of the functions of the State in its relation to medicine, nor does that education necessarily end with the fitting of the student for his life work, but may legitimately be extended to propaganda which informs and educates the public in all matters pertaining to hygiene, affecting not only the individual, but especially when through the individual the community at large is affected.

Prophylactic medicine must always be a function of the State. Improper hygienic conditions or carelessness in the quarantine regulations of any person or locality is a menace to all, and that which affects the welfare of all citizens must be dictated and controlled by the only power that has authority over all the people. It cannot be left to the individual opinion or whim.

Those mentally and morally deficient must have State care. Not simply that these unfortunates must be cared for in the most efficient way possible, but because the welfare and safety of all citizens demand it. To these we may add the indigent from whatever cause, because they are a public charge and for humanity's sake must be cared for. But I think I may safely say that outside of these latter classes when the State in any form undertakes the practice of medicine and cure of disease among its citizens in private life, it has gone beyond that which is best for the progress of the science and art of medicine, and for those who should be served and benefited by it.

Some have likened the State in the practice of medicine to its function in education, but the one is of general interest and moment in a large sense, while the treatment of disease is primarily and almost wholly an individual matter. In all matters pertaining to the citizen's individual and family life he must be left as free as in matters of conscience and religion, and restricted only when it affects the general good.

The American citizen is sometimes called a faddist, and one of his fads is to fly to legislation to cure any and all ills that exist. Wise, sane, needful legislation is a great aid to betterment of conditions, but unless the need precede the legislation, and we, the people, be sufficiently educated to see the need and demand the remedy, mere legislation is worse than useless.

In 1883 Bismarck caused to be legally adopted in Germany compulsory health insurance, to appease the clamor of the proletariat and thereby strengthen the monarchial form of government. It doubtless temporarily, at least, accomplished his purpose. Statistics do not prove that it was of lasting good to those supposed to be served by it.

If compulsory insurance or state medicine is needed it must be shown that a considerable number of people are not getting and cannot get proper medical and surgical care under existing conditions; that too much sickness exists; that time lost by sickness is greater than should be under proper conditions, and consequently

*President's address presented at the Indianapolis session of the Indiana State Medical Association, September, 1921.

unnecessary suffering, needless loss of time, causing too great financial loss to employer and employed. Its continuance can only be justified by its alleviating or curing these conditions. It does not follow that because conditions are not ideal as they exist, that they will be so if free medical and surgical treatment are provided for each individual. In fact, something for nothing or without due effort on the part of the recipient is a curse rather than a blessing. A committee having the matter in hand estimated it would cost seventy million dollars to carry out the provisions of such a measure, compulsory health insurance, in Illinois. Such a drain on the resources of a state can only be justified by the lessened morbidity and mortality. Have such results maintained where such measures have been tried?

If we compare those European countries where such methods have been tried we not only find their sickness and death rate greater than those around them, who do not have compulsory insurance, or state controlled practice of medicine, but that matters are worse with them than before the advent of such methods. Quoting from an address by Dr. Chas. J. Whalen: "Not only do the wage-earners of Germany and Austria lose more time through sickness under compulsory health insurance laws than in the United States without such laws, but it is also interesting to note that it has produced in the habits of the German and Austrian workers a tendency to become sick, to imagine they are sick, or to make believe they are sick. The figures are illuminating. In Germany out of every 1000 insured wage-earners 36.7 were listed as sick in 1890, and 45.6 in 1913. In Austria the corresponding figures were 45.7 in 1890, and 51.8 in 1913. In Germany the average number of days for each sick member increased from 16.2 in 1890 to 17.4 in 1913. The average number of days' sickness per insured member, which was 5.9 in Germany in 1885 when the law had just gone into effect, increased to 6.19 in 1890 and 9.19 in 1913, while the Austrian statistics from 1890 to 1913 show an increase from 7.98 to 9.45 days. Not only did the duration of sickness per person increase, but more persons were reported sick in Germany and Austria in 1913 than in 1890, showing compulsory health insurance laws did not prevent sickness, nor minimize its duration and, therefore, did not promote efficiency."

"In 1912 the death rate in Germany was 15.6 per thousand population. In Austria 20.5, and in Hungary 23.3. Now compare these figures with the mortality ratio in several countries which had no compulsory health insurance laws in effect. In the same year the death rate in Australia was 11.2; in New Zealand, 8.9; in Sweden, 14.2; in Switzerland, 14.1; in Belgium, 14.8; in Denmark, 13; in The Netherlands, 12.3; and in the United States 13.9, which was further reduced in 1915 to 13.5."

"This low rate was obtained despite the fact that the ordinary tendency to disease is aggravated by a great variety of climates in the United States, by diversity of races represented in our population and the fact that the United States has kept its doors open to millions of immigrants unused to our changes of climate; many of them wasted by toil and privation in their homeland."

Hon. Francis Neilson, ex-member of British Parliament, a student of political economy, speaking before the Chicago Medical Society in December, 1916, said that social insurance in England is a dismal failure. He says one has but to investigate all conditions to prove it. Under the laws the people are entitled to the best medical service money can buy, but in countries which have adopted compulsory health insurance they are getting the worst medical service in the world.

Alfred Cox, M.B.B.S., Medical Secretary of the British Medical Association, in a series of articles in May 7, 14 and 21, 1921, of the *A. M. A. Journal*, brings Britain's experience with national health insurance up to date under the title of "Seven Years of National Health Insurance in England". (A Retrospect.)

He evidently tries to state the matter very completely and fairly. He urges the consent and cooperation of a large majority of the doctors wherever the plan is tried. That without aid and cooperation of the parties most concerned the plan must be a failure. England's funds are provided from the three-fold source: The regular payment by the head of the house benefited, the company in whose employ he is, and the government. His report as a whole is favorable to the system, though he says there is great variety of opinions both among the doctors and the laity. He states that the average doctor engaged in the practice is probably better paid than before compulsory insurance went into effect, because previously to that many of them did contract work at a lower per capita fee than the government pays. That a better feeling exists between the profession and authorities than at first because many of the points of contention have been ironed out and the doctor is getting more recognition in the work than formerly. No statistics are given at any time; all statements are based on the writer's opinion from his own observations. His conclusions in regard to its application to America are against rather than for the system.

He advises that some organized plan should be worked out by the profession and government that those unable to provide their own

medical and surgical care should be more definitely provided for, not leaving it to the unorganized effort and charitable instincts of the doctor at his own expense. He concludes, however, with the statement that unless America has a very large percent who are unable to provide for themselves it should not be tried on this side of the water.

I have quoted two men probably alike competent, from different angles, to express an opinion, probably both alike sincere, and yet widely different conclusions are reached as to local effects. May I not emphatically suggest that we must take into consideration the wide difference in conditions in America and even in England, probably the most favored of European countries. What will appear good to a Briton will not satisfy an American. Such arrangements are un-American. The glory of America has been freedom for all within her borders and that freedom as absolute as consistent with good government, and the rights of others. Since the sailing of the Mayflower till the present day men have sought our shores that they and their families might enjoy a freedom Europe did not offer. Not only a freedom that the early pioneers sought (to worship God according to the dictates of their conscience), but a freedom to win and enjoy by their own efforts all that pertains to man's estate. Are we now going to offer them and their descendants a stone instead of bread, or a venomous something which, if offered and accepted, will at last bite like a serpent and sting like an adder.

Dr. Vaughn says, "There must be a minimum of interference with the relation which has so long existed between the physician and his patient and which, on the whole, has proven so satisfactory to both. The patient must have the right to select his physician, and the physician must have the right to study and prescribe for his patient as he sees fit. The pecuniary reward that comes to the physician must be determined between himself and his patient. There must be no state regulation in these methods. The panel system, as employed in England, is good for neither physician nor patient. There must be no state appointed doctors to administer to the needs of those who are able to pay medical fees."

"In armies it is necessary to have medical officers, and those over whom they are placed must accept the services of such medical officers whether they like it or not. We admit this is essential in military organizations, but we believe that such a practice would be harmful in civil life, and would lead to deterioration on the part of medical men and to discontent on the part of those whom they serve."

All plans for state medicine or compulsory insurance leaves out of consideration one of the most important parts in the practice of medicine—the personal element. They seem to think that medical service can be bought and sold like ordinary merchandise for so many dollars. A father disappointed in the outcome of his son's training and development, complained in his chagrin and disappointment, "Why, I gave him from earliest babyhood everything money could buy." The retort was, "You have failed because you have given him so little money cannot buy." Do you want in any capacity, especially in times of sickness and suffering a time server who gives only what money brings? He is a poor physician who does not give more than his technical skill and his drugs. That element of every good physician which cannot be bought in the marts of trade—that human sympathy and understanding—often turns the tide and saves life and gives happiness that is lasting. Can you expect it to any degree when patients are treated at so much per, because a state chooses some man to do a certain task?

When you rob a man of the right to care for his own you rob him of the most divine and ennobling right that the state or God himself has ever bestowed upon a human being. "He that looketh not after his own and especially those of his own household has denied the faith, and is worse than an infidel." Why force him into such a position?

A claim made in justification of this procedure is that men are not able to supply the money to secure medical services for themselves and family. When that is true conditions are not normal. Either there has been unusual demands or the breadwinner has been unable through sickness or other unusual misfortune to meet such demands.

If there have been no unusual conditions either in the demands or the individual's ability to earn a livelihood, then the question ceases absolutely to be a medical one, and becomes a social or economic one. Then there is no more excuse for giving these families free or partly free medical aid than there is for paying their rent or grocery bill in whole or part, which would at once put them on the pauper list. Any donation in any line is only palliative, not curative.

When any able bodied man under ordinary circumstances cannot care for his dependents, he is either paid too little for his work, or he is putting to poor use the money he earns.

It is impossible to even mention the many objections to this pernicious proposal whether in the form of State medicine or compulsory

health insurance, but to me the most vital is the loss of self-respect that comes to any man when he accepts help and brands himself as a dependent when the thing should come to him as his right in payment for his labor, he soon becomes lethargic and indifferent. The American soldiers were noted for their resourcefulness in times of stress, and that came not from a few months' training, no matter how effective, but because all their lives they had been free, independent citizens, and depending upon their own resources and when the crisis came they met it.

One of the striking things in this discussion is that those supposed to be benefited by such legislation and those most concerned in its enforcement if enacted into law, the laborers and the doctors, do not favor it. James W. Sullivan, Mark A. Daly and Samuel Gompers, in papers read at the 20th annual meeting of the National Civic Federation, January 30th, 1920, at Hotel Astor, all oppose such laws. Samuel Gompers in conclusion said, "But I do want to take this occasion just now to say that it has come to me recently some person has declared that Gompers has been won over to compulsory health insurance. I have already made my answer, which is, that I am unalterably opposed to it."

One of the greatest incentives that a physician or surgeon has is his independence of action, that his success is limited only by his ability. Why should the state in times of peace take this right and demand his services under many restrictions?

You do not need to go to countries where such laws are in effect to learn what it will do for the quality of service given and the general progress of medicine. One of the greatest incentives to labor is the individual recognition and reward. Many may do splendid work for the work's sake, but we all will do better when we add to that the personal reward for personal accomplishment. The quality of service is bound to deteriorate if the state as our taskmaster says, go here or go there.

The challenge of State medicine to every practitioner is better work, more intelligent, conscientious work. Let us look askance on any plan or scheme that takes the control out of the hands of the men who have nobly and loyally served their day. Let no plan, however alluring and attractive, be accepted that robs the physicians of any of their freedom or may lead to the limitation of any of their rights as physicians.

TO LESSEN THE ANESTHETIC RISK

F. N. SHIPP, M.D.
CRAWFORDSVILLE, INDIANA

Since 1847, when chloroform was introduced by Simpson, who regarded it as more portable, more manageable and powerful, more agreeable to inhale, and less exciting than ether, and an agent giving greater control and command over superinduction of the anesthetic state, the medical profession has been divided in its opinion between ether and chloroform as the anesthetic par excellence. Each has had its advocates who could see no virtue in the other, but the surgeon or anesthetist of today who would insist on the use of either ether or chloroform in every case, to the exclusion of the other, shows a lack of knowledge of the therapeutics of these drugs and bases his preference on the fact that he has used one or the other for many years and has never had an accident. Such arguments, mentioned at the beginning of this article, as brought forward by Simpson in his advocacy of chloroform, are absolutely worthless in the selection of an anesthetic, because they do not take into consideration the safety of the patient. The question to be decided by the anesthetist is not whether ether or chloroform is more portable, less exciting, more pleasant to inhale, but in a given individual case which anesthetic is least dangerous to the life of the patient.

Statistics regarding the relative fatality of anesthetics point to greater danger from chloroform than from ether, but all statistics on the subject are unreliable, as it is impossible to exclude contributory causes. There seems no doubt that failure of both heart and respiration, without known cause, are more frequent from chloroform than ether. There is no argument so clinching as this for the universal use of ether except in cases in which ether is positively contraindicated. There is nothing more deplorable than sudden death from an anesthetic given for some minor operation; it is heart breaking to the anesthetist and surgeon and unforgivable by the family of the patient.

It generally is conceded that the after-effects of ether are more marked than those of chloroform; that post anesthetic pneumonia and nephritis are more frequent following ether, though this view is not accepted by all investigators. I believe we can all agree that there is an element of danger in any anesthetic, but that the danger of sudden death from undiscoverable cause occurs more frequently from chloroform. In fact sudden death from ether is a rare occurrence. If we now eliminate the small percent of patients in whom ether is positively contraindicated and choose the anesthetic with the one thought as to which anesthetic presents the minimum risk to the patient, ether will be the indicated agent in the vast majority of cases.

Having selected the anesthetic most suitable to the patient, the anesthetic risk may be reduced further by the selection of an administrator of skill and judgment. I believe that if ether is the anesthetic of choice, and it is administered by a capable anesthetist, the risk of a fatality during the anesthetic state is so remote that it needs little or no consideration.

It is reasonable to believe that any method that will decrease the amount of ether inhaled during an operation will decrease the post-anesthetic danger. The first consideration in this respect is the anesthetist. Doctors who are familiar with patients prior to operation know that in most cases the fear and dread of the anesthetic far exceeds fear of the operation. A person in the grip of this fear will resist the anesthetic, unconsciously fighting against it, and require a large amount of the drug to produce surgical anesthesia. If this fear of the anesthetic can be allayed, the quantity of ether used during the first and second stages of etherization will be lessened materially. This is not a theory but a fact I have observed repeatedly, and I believe will be substantiated by all anesthetists.

It is unfortunate that the anesthetist is frequently a stranger to the patient and is first brought into the patient's presence shortly before the administration, thus being placed at a distinct disadvantage. If the administrator is able to gain the confidence of the patient it will go far in overcoming the nervousness and dread of the anesthetic. It is rather difficult to obtain the proper relation that should exist between patient and anesthetist when they are unknown to each other until shortly before the anesthetic is to be given.

At least a few minutes should be taken to explain to the patient the sensations experienced during the first stage of etherization, instructing him or her how to breathe and to realize how little danger there is from the anesthetic. During the first stage much may be accomplished by talking to the patient and especially concerning the safety of the anesthesia. I believe it was Murray who said that many patients could almost be talked to sleep. But if there is a place to talk during etherization there is also a place to act, a time when the anesthetic must be pushed. Only experience will teach when this point has been reached and it is of the utmost importance that the administrator know this, otherwise the patient is kept in an excited, semi-anesthetized state for an indefinite time, the operation delayed, and the quantity of ether inhaled increased far beyond what is necessary. Surgical anesthesia having been obtained, the object is to keep the patient relaxed on the smallest quantity of ether possible, and again it is the skill and experience of the anesthetizer that accomplishes the most satisfactory results.

Second in importance to an experienced administrator in producing and maintaining surgical anesthesia on a minimum quantity of ether is the hypodermic use of morphine and atropine prior to the administration. Of course it must be understood that no hard and fast rule can be laid down for the use of these drugs as a preliminary to the anesthetic; each patient coming to operation must be considered individually and idiosyncrasies taken into account, but after eliminating the cases in which morphine and atropine are contraindicated we have an overwhelming percent of patients who will derive a marked benefit from their use, principally because the amount of ether inhaled is less in cases so treated. A brief review of the therapeutics of opium will, I believe, convince the most skeptical of its value in the matter under discussion. I have spoken of the fear so constantly present in patients coming to operation and the part it plays in the administration of an anesthetic. Fear is an emotion of dread. All emotions are agitation of mind or excitement of sensibility depending on nervous reactions. Hare says the dominant action of opium upon man is to produce nervous sedation when given in small doses. In this respect morphine is positively indicated as a pre-anesthetic adjunct. Therapeutic doses of morphine have no effect on the circulation, and if any on respiration act as a feeble stimulant. As to atropine, it stimulates the cardiac muscle and is also a stimulant to the respiratory center, but its chief value when given prior to ether administration is its actions on secretion. Ether causes a free secretion of mucus in the fauces: this excess mucus and saliva soak the gauze of the inhaler which interferes with the proper inhalation of the anesthetic. To a certain extent this excessive secretion can be controlled with atropine. Therapeutically, therefore, we find valid reason for the use of morphine and atropine as a pre-anesthetic measure, and from personal observation and comparison of many cases in which these drugs were and were not given I feel I can state positively that there is a practical benefit from their use in that they shorten the first and second stages of etherization and maintain surgical anesthesia on a reduced quantity of ether.

Let us now consider the use of short term anesthetics in conjunction with ether, and in this respect I wish to make special reference to ethyl chloride. The use of nitrous oxide, ethyl chloride or any short term anesthetic as a preliminary to ether have this to recommend them: that they eliminate the unpleasant first stage of etherization, shorten the second stage and thus lessen the quantity of ether inhaled. All of

which is of distinct advantage to the patient. Of the short term anesthetics ethyl chloride has proved eminently satisfactory for many years in my work, not only as a preliminary to ether but in selected operative cases of short duration, replacing other anesthetic agents entirely. In more than five hundred administrations of ethyl chloride no untoward effects have been noted. It was used in conjunction with ether a comparatively few times, but proved its worth by overcoming the first and shortening or eliminating the second stage of etherization. The large percent of my experience with this anesthetic has been for dental operations, though I have used it repeatedly for short operations of various kinds. The ages of the patients have varied from five to seventy years. Very few dental cases had any preliminary preparation for the anesthetic, yet there were no cases of cyanosis nor any change noted in the circulation. No case showed danger symptoms during the administration, and recovery was rapid. Few patients were nauseated, and in this respect it must be remembered that more or less blood is swallowed during dental operations and that frequently the anesthetic was given shortly after a hearty meal. A stage of excitement is almost unknown; complete anesthesia is reached in an average time of one minute, and with inhaler removed the available time for operating is from one to one and a half minutes. For children it seems a perfect anesthetic for short operations, as the odor is pleasant, it causes no throat irritation, no cyanosis or undue bleeding, and the recovery is rapid and complete. You do not get the muscular relaxation from ethyl chloride you do from ether, but there are many operations of short duration, five to ten minutes, where it can be employed successfully. On one occasion I kept a patient anesthetized with this agent seventeen minutes, with rapid recovery and no untoward effects during or following the anesthetic. The inhaler that has given me the best results consists of a rubber face piece connected to a right angled piece of metal tubing to which is attached a rubber bag. An opening at the angle of the tubing permits the spraying of the ethyl chloride directly into the bag. The air is controlled by closing this opening with finger or thumb. The spray of ethyl chloride is the best form to use. Ethyl chloride presents several advantages over nitrous oxide and other short term anesthetics, not the least of which is the portability of the inhaler and the anesthetic agent, all of which can easily be carried in a coat pocket. The simplicity of its use, coupled with its safety and the fact that it is adaptable to certain operations of short duration makes ethyl chloride a valuable member of the anesthetic family.

To sum up: The anesthetic risk can be lessened by the proper selection of the anesthetic suitable to the individual case; the anesthetic should be given by an experienced administrator; morphine and atropine are indicated and should be used except when there exists some positive reason for withholding them; the use of a short term anesthetic as a preliminary to ether; the use of ethyl chloride to the exclusion of other anesthetic agents in selected cases where it is suitable.

ACIDOSIS

M. W. LYON, JR.
SOUTH BEND, INDIANA

The term acidosis was originally applied to the abnormal metabolic state in which there is an excess of acetone, diacetic acid and beta-oxybutyric acid in the blood whose normal carbon dioxide carrying capacity is thus interfered with. Since then other acid bodies have been found in the blood in abnormal states and the term now usually includes all those abnormal states in which there is an unusual production of acids or in which there is an excessive retention of acid bodies in the blood. The condition in which carbon dioxide, the anhydride of carbonic acid, accumulates in the blood in cases of cardiac and respiratory failure is usually not included in the term acidosis. A more accurate definition of acidosis is the bodily state in which the capacity of the plasma for carrying carbon dioxide is reduced below 50 volumes percent. While it is customary to speak of acid bodies in the blood yet as such they do not exist. The blood in life is always alkaline and as rapidly as acids are produced by normal and abnormal metabolism they are neutralized by the alkalis of the blood and excreted by the kidneys. Death usually occurs before the hydrogen ion concentration of the blood reaches neutrality or pH7. Acids administered to dogs experimentally cause very rapid death when the pH reaches 6.9. Diminished alkalinity describes the condition more accurately so far as the chemistry and physics of the condition is concerned, but it is not so expressive of what is occurring as the term acidosis.

While acidosis is usually thought of as a condition of the blood and more particularly of the plasma, yet as all the tissues of the body are bathed and saturated by the plasma the condition of acidosis is found throughout the body generally. It is probably more accurate to say that the acids of catabolism are formed in the tissues and are carried away by the plasma.

Among the laity and among not a few physicians the condition of acidosis is referred to as a pathologic entity and to state that a patient is suffering from acidosis serves as a satisfying

diagnosis. Acidosis, however, is only a symptom of certain clinical entities. Often it is the most important symptom and one to be combatted vigorously. It never constitutes a diagnosis by itself any more than hyperpyrexia can be termed a diagnosis.

The substances concerned in maintaining alkaline blood are sodium bicarbonate, $NaHCO_3$; disodium hydrogen phosphate, Na_2HPO_4; and proteins. By far the most important of these is sodium bicarbonate. In normal metabolism carbon dioxide is the most common acid produced. It is loosely held in solution by the alkaline blood and as the latter passes the pulmonary capillaries carbon dioxide escapes into the alveolar air. When other acids are present, and they always happen to be stronger than carbon dioxide, they unite with the plasma bicarbonate and so interfere with the carbon dioxide carrying ability of the plasma. Carbon dioxide consequently accumulates in the tissues and as one result of this the respiratory center of the medulla is stimulated and forced respirations occur. The attempt on the part of the organism is to get rid, as rapidly as possible, of the little carbon dioxide that can be carried by the plasma by means of increased pulmonary ventilation. By this process more air passes in and out of the lungs and that coming out contains less carbon dioxide than in the case of normal breathing and metabolism.

The increased respiratory effort, or hyperpnea, just referred to constitutes the one characteristic clinical sign of acidosis and that is present only when the condition is fairly well advanced. "The only symptom that may be considered positively pathognomonic of acidosis is hyperpnea or deep breathing, the so-called 'air hunger' of Kussmaul, the cause of which has already been explained. The breathing of acidosis is deep, it is not usually increased in rate, and differs markedly from the shallow, rapid breathing of pneumonia or the labored breathing of obstruction. It is pauseless and though the several inspirations may vary in depth so that a modified Cheyne-Stokes respiration may be present, in general the excursions of the abdomen and thorax are nearly the same with succeeding respirations. The most striking is the amplitude of the respirations and the distinct effort with which they are accomplished. They are heaving, the chest rises and falls with each respiration and often the accessory muscles of respirations are brought into play." As the blood is well aerated and the hemoglobin intact, "There is no cyanosis except in the presence of cardio-respiratory disease. A cherry-red color of the lips is occasionally observed but is of little diagnostic value. Drowsiness may be seen as an accompaniment of acidosis due to acetone bodies. Vomiting is not a symptom of acidosis." (Howland and Marriott, 1918.)

The acids concerned in the production of acidosis and the conditions in which they are found are as follows:

1. Acids of the acetone group, CH_3-CHOH-CH_2-COOH, beta-oxybutyric acid, CH_3-CO-CH_2-COOH, diacetic acid. CH_3-CO-CH_3 is the formula of acetone. Each of these may be successively formed from the preceding by oxidation. There is much evidence to show that beta-oxybutyric acid may be formed from diacetic by the reverse process of reduction. It is universally conceded that the two acids are results of fat and fatty acid catabolism (Wells, p. 550) and perhaps of protein catabolism. They are formed when the ability of the body to handle carbohydrates breaks down as in diabetes or when no carbohydrates are present as in cases of starvation, etc. They are frequently found after anesthesia, perhaps as result of the coincident restriction of diet as much as to the specific effect of the anesthetic. Acetone acidosis is also found in the toxemias of pregnancy, in infantile marasmus, in cyclic vomiting (even aside from the lack of food caused by the vomiting), in Asiatic cholera (Sellards and Shaklee), in inanition and cachexia. It is particularly common in children, disorders in them resulting in acidosis which would not cause it in adults. More common than acidosis in children is acetonuria and acetonemia without accompanying acidosis.

2. Lactic Acid. This is one of the normal products of catabolism. It is found to excess in severe muscular work, in convulsions, in acute destruction of the liver as in phosphorus and chloroform poisoning, and in severe diarrhea in infancy (Marriott, 1920). Lactic acid is one of the products found in methyl alcohol poisoning and along with formic acid made at same time constitutes an important form of acidosis (Harrop and Benedict). Lactic acid is also found in excess in the toxemias of pregnancy (Wells, p. 559).

3. Formic Acid. Probably the most important condition in which formic acid occurs in excess in the body is in methyl alcohol poisoning. Its relation to methyl alcohol is seen by a comparison of the formulas of the two, methyl alcohol, CH_3OH, plus O_2 yields formic acid, HCOOH and water H_2O. Along with the lactic already referred to the acidosis caused by it constitutes an important symptom of wood alcohol poisoning and one to be combated by alkali therapy (Harrop and Benedict).

4. Acid Sodium Phosphate, H_2NaPO_4. This acid salt is normally excreted by the kidneys and is one of the chief factors in rendering the urine acid. One of the normal renal functions is excretion from the alkaline blood of this acid salt. In nephritis this function is impaired. In severe

nephritis, acute or chronic, acidosis of sufficient degree to cause death may result (Chase and Myers).

5. Unknown organic acids such as have been found in lobar pneumonia (Lewis and Barcroft, Palmer).

6. It is possible that ingestion of large quantities of mineral acids such as hydrochloric or sulphuric or of acid salts, or of certain organic acids may yield an acidosis similar to that brought about in experimental animals by intravenous or enteric administration of such substances. Such cases of acidosis in man must be comparatively rare and unimportant from a practical standpoint. Most of the organic acids and their salts after entering the body become oxydized to carbonates and as such increase the alkalinity of the blood.

The methods of diagnosing acidosis aside from the symptom of hyperpnea are essentially laboratory procedures. Two of them are sufficiently simple to be termed clinical or bedside methods, but the others require considerable apparatus and skill.

CLINICAL METHODS:

1. Estimation of the carbon dioxide tension of the alveolar air. As the amount of carbon dioxide in the lungs is proportional to that carried by the blood the determination of the amount in the lungs or alveolar air is a good index of the state of acidosis. Several methods for doing this have been devised. Probably the simplest and one clinically satisfactory is Marriott's colorimetric method by bubbling air exhaled into a rubber bag through a standard colored solution and noting change of color due to CO_2 (Marriott, 1916). (Instrument obtainable from Hynson, Westcott & Dunning, Baltimore.) Other methods of more complexity are those of Fredericia and of Haldane. In health the carbon dioxide tension of the alveolar air is 45 to 40 mm.; 35 to 30 mm. represent mild acidosis, 20 mm. indicates a dangerous degree of acidosis; in coma due to acidosis it may be reduced to 10 mm.

Closely allied to this method of determination of the alveolar air carbon dioxide is the one recently described for determining the amount of acetone in the expired air (Higgins). It should be noted, however, that there may be marked acetonemia and acetonuria without a corresponding acidosis.

2. Sellards' alkali tolerance test. In normal adults the ingestion of 5 to 10 grams of sodium bicarbonate is sufficient to render the urine alkaline. In cases of acidosis 4 to 10 times this amount may be required. This test is very easily applied and in addition to being a test of acidosis it is an excellent therapeutic measure (Sellards, 1912).

Methods by examination of urine: These all depend upon a normally acting kidney. They are comparatively easy to make, but show less accurately the true state of acidosis than do examinations of the blood.

1. Detection of acetone bodies, acetone, diacetic and beta-oxybutyric acids. Acetone and diacetic acid tests are readily done as a routine on all urines. One of the simplest and cleanest methods of testing for acetone in urine is to add to 5 cc. of urine in a test-tube ½ cc. of a 2 percent solution of sodium nitroprusside in a 1 percent solution of acetic acid. (It is unnecessary to use weights and measures in making this solution or doing the test. The nitroprusside-acetic acid mixture will keep several days.) The urine and nitroprusside mixture is then overlaid with strong ammonia water. A purple ring denotes acetone. Acetone in the urine is only suggestive of acidosis and should be followed up by other tests. Acetonuria without acidosis is of very common occurrence in children. Gerhardt's well known ferric chloride test (Stitt, p. 581) for diacetic acid is simple and good but open to two sources of error. In certain alkaline urines the reaction may appear (Maxwell) while a purplish red color is produced after the ingestion of salicylates, such as the much-used aspirin of today. In case of doubt the urine should be boiled, a procedure which will expel the diacetic acid but not the salicylates, and then tested in the usual manner. The test for beta-oxybutyric acid while not difficult is longer and not adapted to routine examination of urines.

2. Determining the degree of acidity of urine. In normal urines the degree of acidity increases as the specific gravity increases. Multiplying the last two figures of the specific gravity in normal undecomposed urines gives approximately the number of cubic centimeters of normal alkali needed to neutralize 100 c.c. of urine, phenolphthalein indicator. High acidity in urines of low or normal specific gravity is somewhat suggestive of acidosis. A more accurate method of determining acidity is to estimate the hydrogen ion concentration of the urine (Anon, p. 243). One of the defenses of the body against acidosis is the formation of ammonia and the neutralization of the acid by the ammonia. The acids are then excreted in the urine not as such but in combination with ammonia. Consequently systemic acidosis may be marked while the urinary acidosis is essentially normal.

3. Estimation of the amount of ammonia in the urine (Stitt, p. 578). Normally about 0.7 gram of ammonia is excreted by the urine daily. In certain conditions of acidosis the amount of ammonia in the urine may reach a total of 5 to

10 grams per 24 hours. The percent of ammonia to the total N in the urine may be increased from the usual 3 or 5 to 30 or 50 percent. The urinary ammonia is comparatively easily estimated by several well known laboratory procedures, especially by the aeration method (Anon, p. 228). The formation of ammonia in the body in cases of acidosis is of much interest as it represents a special defense against that condition. This special defense is most marked in the acidosis due to diacetic and beta-oxybutyric acids. In other conditions of acidosis ammonia formation is almost negligible, and is essentially lacking in the acidosis of nephritis. The estimation of the ammonia in the urine is usually much simpler than the estimation of the acid bodies and yields more valuable information.

Methods by examination of the blood. Just as in diabetes and nephritis examinations of the blood yield information of more value than the more frequently made examinations of the urine, so in acidosis blood examinations yield more valuable information than urine examinations.

1. By far the most important of these methods and one by which the degree of acidosis may be accurately stated is that in which the carbon dioxide combining power of the plasma is determined by the well known and comparatively easily used Van Slyke apparatus (Van Slyke, Stitt p. 274, Anon p. 264). The test itself is spectacular as one sees the carbon dioxide escaping from the plasma into a graduated tube by the addition of sulphuric acid. It also shows graphically what happens in the body when the carbon dioxide is displaced by acidosis into the tissues. Normally 100 c.c. of plasma will hold 80 to 53 volumes of carbon dioxide. In mild acidosis without symptoms the plasma will hold 53 to 40 volumes, in moderate acidosis with symptoms referable to the acidosis 40 to 30 volumes, and in very severe acidosis 30 volumes and less. The lowest values in fatal cases are about 20.

2. A less accurate and less spectacular method than Van Slyke's but using simpler and less expensive apparatus is Levy, Rowntree and Marriott's device for determining the hydrogen ion concentration of the serum or plasma by a colorimetric method. pH 7.6 to pH 7.8 is normal while in conditions of acidosis figures of pH 7.55 to 7.2 are obtained. pH 7.0 is the point of neutrality. In one of their experiments on dogs by intravenous injections of hydrochloric acid pH 6.9 was obtained, the animal dying about 20 minutes later (Levy Rowntree and Marriott, 1915).

3. A similar method is determining the alkalinity of the plasma by microtitration (Stitt, p. 568).

4. Sellards' serum test. One cubic centimeter of serum is added to 25 c.c. of neutral absolute alcohol, shaken and the whole filtered. A drop of phenolphthalein solution is added and the whole filtrate evaporated to dryness. Normally a reddish purple color develops; in severe acidosis, there is a faint pink color or none at all, but the addition of a drop of water brings out a pink color. In extreme acidosis water fails to bring out the color (Sellards', 1914).

The chemistry of acidosis points the way to treatment. The therapeutic substances employed are dextrose, alkalis, principally sodium bicarbonate, and water.

In acetone-body acidosis when the fats and possibly the proteins are being oxidized to diacetic and beta-oxybutyric acids and the available sugar is apparently gone the administration of dextrose is indicated except in the acidosis of diabetes in which condition the body's ability to handle dextrose is broken down. When the alimentary tract will tolerate it dextrose may be given by mouth in 5 to 10 percent solution about as frequently as liquid nourishment is usually given. If not tolerated by the stomach it may be given by rectum in 5 percent solution in bulk or by the drip method. The most certain method and one often yielding brilliant results is by intravenous injection of a 10 percent solution, 50 c.c. for a very small infant, 500 or even more for an adult. The dextrose solution should be filtered and autoclaved. It should be administered slowly so as not to place a sudden strain on the circulatory apparatus.

In acidosis from any cause alkalis are indicated, but in the acidosis of diabetes the results are not satisfactory. Sodium bicarbonate may be given by mouth in doses of 1 to 4 grams at a time. It may be given rectally as in the case of dextrose. Intravenously it often gives brilliant results in cases of extreme acidosis. For intravenous use a 4 percent solution is employed. 50 to 100 c.c. for infants, 200 to 300 c.c. for larger children and 500 c.c. for adults. It should be prepared by adding the dry sodium bicarbonate weighed out on sterile scale pans, handled with a sterile spatula, and adding it to freshly distilled and sterilized water. After once prepared it cannot be sterilized as in heating one molecule of carbon dioxide is liberated and the irritating more alkaline sodium carbonate results. Dry sodium bicarbonate is essentially sterile. Its solution does not keep, but breaks down spontaneously into the carbonate. It may be combined with the dextrose solution and the two substances given together. Acidosis is of such common occurrence among children that it is often well in treating acutely ill children to anticipate acidosis and administer sodium bicarbonate or the more palatable sodium citrate.

which finally appears in the blood as sodium bicarbonate, as a prophylactic measure. When the urine has become alkaline or has an acidity so low that 100 c.c. may be neutralized by about 10 c.c. of normal alkali, the alkali therapy should be lessened or discontinued.

In acidosis associated with diarrheas and vomiting the body usually becomes rapidly dehydrated and the kidneys unable to excrete properly, water is urgently needed. It should be given liberally by mouth if possible. If not it may be given rectally in the form of salt solution. In urgent cases salt solution may be given intravenously in about the same quantities as for the dextrose and alkali solutions already mentioned. In infants up to 300 c.c. may be given intraperitoneally by means of a short-beveled needle inserted in the midline below the umbilicus or just outside the rectus muscle at the level of the umbilicus in the left side to avoid puncture of the liver. The buffered solution of Ringer (sodium chloride, 0.7 percent, potassium chloride 0.03 percent, calcium chloride 0.025 percent), is better than the usual salt solution (Howland and Marriott, 1918; Marriott, 1920).

"THE PHYSICIAN"

RELATION OF THE PROFESSION TO SOME DISEASE HABITS*

By

FRANK B. WYNN

INDIANAPOLIS, INDIANA

That we are creatures of habit is a most trite but true saying. The lower animals are governed by it even more than we. The small brained swine respond with regularity to the feeding hour, more from habit than hunger. The horse soon learns to turn at the end of the corn-row, without even being directed.

All habits are physiological in the manner of their production and development. In the main there occur the afferent impulses awakening central nervous reactions and giving rise to efferent impulses which bring about peripheral reaction of gland, muscle or tissue. Closely related parts and centers are affected, but to a lesser degree. The physiological fact to remember is that there are certain paths of conduction and definite centers of response which become more or less permanently changed from the traveling or impact of these impulses. Of all points of contact and stress that which probably suffers most is the nervous center. Here then is where we must look for the chief lesion arising in habit formation. The processes of induction may vary, but the method of physiological development will be the same whether it be the liquor habit, the opium habit, postural habit or the habit of constipation. If we keep constantly in mind the truth, proved by reasoning and clinical observation even if not readily demonstrable in the laboratory, that the chief point of injury in habit formation is the nerve center, we can realize more easily why habits are difficult to eradicate; and if we would pursue the wiser course, how very important that the profession, collectively and individually, should take every means possible to prevent habit formation.

When mention is made of habit formation in relation to medical practice thought almost invariably centers upon chronic alcoholism or drug addiction. One purpose of this discussion is to show that the subject has a vastly wider application.

A few years ago when alcohol was king of the habit-forming realm, its victims were found by scores in the larger public institutions. Although, as practitioners, we may chafe under the curtailment of our rights and liberties in the matter of prescribing, the convincing fact stands out and compels admission of the truth that prohibition has swept from medical sufferers a great host who came in the wake of

*Sixteenth of the series of articles by Dr. Wynn appearing regularly in THE JOURNAL.

alcoholic abuse. Now their number is almost negligible and the subject scarcely requires mention in this essay.

In a similar manner, opium and its derivatives under the restrictive influence of the Federal law, have shown a wholesome tendency to conservatism in their administration by the profession. And most fortunate for the chronic sufferers themselves, the purchase of habit forming drugs by the patient upon his own initiative has been made almost impossible. Quack remedies which formerly contributed largely to the ranks of opium habitues are now put under ban. The outcome of this evolution in wiser opium administration is that whoever now acquires the opium habit does so chiefly through thoughtless administration by practitioners who give these remedies over too prolonged a period or for conditions which might be treated even better by other remedies and measures.

The development of the opium habit is so insidious in its onset and fearful in its consequences, that every practitioner should early in his career lay close to his heart the grave moral obligation placed upon him in this matter. Toward no one is this more necessary than the physician himself. The stress of his life, its irregularities, his acute mentality and conscientious responsiveness to the physical and mental troubles of others, make a heavy drain upon his nervous reserve. Therefore he becomes good soil for the development of functional nervous trouble with its attendant irritability and insomnia. The soothing anodyne or the sleep-giving hypnotic tides the overworked physician through an ordeal; and then comes another and another trial of strength and endurance calling for temporary support. Before he realizes, he is depending upon these instable props to hold up his nervous equilibrium. For him, most of all, they are not a safe foundation. They crumble and leave his professional career a wreck. Who cannot name among his professional acquaintances a number of such—generally young men of brightest promise. The records of sanatoria and large hospitals show many of these pathetic figures who arouse one's deepest sympathy. Not rarely the picture is made still more touching by the wife who has also been drawn into the vicious habit stream. These uncanny facts are offered not so much in criticism as in exhortation that in the case of our own families we should avoid the use of opium or powerful hypnotics. Where the indications for these remedies exist, put the responsibility of their administration upon a brother practitioner.

The position here set forth is not to be construed as raising any question concerning the extreme value of the opium group of remedies, when wisely prescribed. The service of morphia to surgery is invaluable. In medicine its soothing effect upon pain, its quieting influence on mental apprehension, cardiac distress, and respiratory agitation are but a few of the emergencies in which it offers not merely comfort, but may constitute an important step in curative therapy. Like fire it is a good thing when properly used, but when carelessly employed becomes a consuming conflagration.

In the giving of opium or its derivatives to any patient, every practitioner should at least have very definite rules of caution from which deviation should seldom be made. Prolonged and continuous administration is not to be permitted except for incurable conditions, or in the aged where habit formation is not so readily developed; and even if formed does not hamper materially the physical well-being or social status. Careful account should always be taken of the temperamental peculiarities of the individual. To those of neurotic type it should always be given with the extremest caution. Its use in recurrent outbreaks of hysteria and migrain is unjustifiably bad practice. Other methods may prove less brilliant in the relief of the patient but they will save the doctor's conscience and protect the patient's future. In no phase of medical practice has the profession been more derelict in this particular than in the treatment of dysmenorrhea. The safe and wise procedure in any case where morphia is indicated is to employ the hypodermatic method—either by the physician himself or under competent nurse control. In this manner the quantity and frequency may be safely regulated and withdrawal instituted early enough to insure the patient's best interest.

Almost equal to opium abuse in recent years has been the indiscriminate use of cocaine—notably in the form of sprays to the upper respiratory tract. It too, has developed a tragic group of victims. Although not so hopeless in prognostic outlook as the morphia habit, cure can only be hoped for through prolonged institutional restriction. Not a few of these cases represent the vain attempt to escape from chronic opium narcotism only to find themselves haunted by two demons instead of one.

In sequence from the foregoing are to be mentioned chloral, the milder hypnotics, chloroform and the analgesics. All have their risks in the matter of habit formation and therefore a corresponding obligation upon the physician to observe caution in their repeated administration. Concerning all of them it may be said with truth, that in the beginning they were heralded by enthusiasts, and especially the pharmaceutic houses, as *not* habit-forming drugs. Wider experience by thoughtful and conservative observers invariably proves the contrary.

In the light of these well established facts let the physician in prescribing habit-forming drugs govern his conduct with the utmost wisdom and foresight.

In considering the tobacco habit I wish in the outset to make clear that I do not belong to that group of "reformers" who feel that, having placed alcohol under universal ban, they should now march upon tobacco. Certainly no one can claim, however, that the latter is a food. Nor can argument be massed to prove to the hygienist that waiting rooms, banquet halls or compartments for men laden with tobacco smoke are wholesome. To the aesthetic minded, who dare contend that radiators, hotel lobbies, and railway coaches are made beautiful by tobacco bespatterment? And to a refined olfactory sense which delights in the perfume of roses or the aroma of spruce forests, is there any divine suggestion in the fetor of a tobacco breath—most of all the nauseating, sweetish odor of the cigarette fiend?

In spite of these criticisms I am compelled to admit that with the vast majority of men, who are users of tobacco *in moderation,* it is a mental solace and comfort. Oftentimes to the chronic insane it is a real boon. What institution worker has not seen the restless and unmanageable back-ward patient made calm and content by tobacco? Many are the husbands, grouchy and irritable from the day's annoyances, who are calmed or sweetened into companionability at the fireside by a pipe or cigar. And who that uses it moderately will not bear testimony to its helpfulness in mental pursuits? How often one observes the thinker, writer, student, or dreamer about to tackle some difficult problem first light his pipe or cigar and then proceed with greater confidence in the accomplishment of the task. What is there about smoking that coordinates and gives momentum to mental processes? It is not the technique of the act. Rather it is a state of mind induced by the mild tobacco toxemia, which shuts out the irritating and irrelevant winds which ruffle and divert the currents of thought. It is near akin to the state of mind into which we lapse with the first approach of sleep at night; or early in the morning when half-waking—times when we frequently find the solution of our problems with startling amazement. In similar manner the smoker sails into a harbor of quiet and safety where he feels confident of himself, and gives expression unhampered to the best there is in him.

Lastly what an unfailing touchstone is tobacco of good-fellowship. It introduces, democratizes, softens old asperities, warms the cockles of the heart and promotes universal brotherhood.

But let not this encomium of the weed deter us from attack of the real and serious harm which may result from tobacco abuse. Every insurance company recognizes the injurious effect of tobacco toxemia upon blood pressure and cardiac rythm, through nerve-center impairment. Recent fashions in smoking are rendering more acute and widespread the evils of tobacco abuse. First of all the World-war has enormously increased the habit of cigarette smoking. That it is more frequently followed by harmful results than other forms of tobacco consumption, is for two reasons—first the tendency to more continuous indulgence; and secondly the prevalent habit of inhaling the smoke deep into the lungs and exhaling it through the nostrils. Carried to excess this sets up a diffuse catarrh of the whole respiratory tract. It is the "smoker's sore throat" which we used to see, projected upwards and downwards more or less over the whole respiratory tract. The protective, ciliated epithelium becomes damaged, making the whole respiratory system more vulnerable to infection by inhalation. From the structural changes of katabolism there is undoubtedly a great deal of protein, autogenous toxemia. This is the most rational explanation of the sallow complexion so frequently observed in those given to excessive consumption of cigarettes.

But the most disastrous inroads of cigarette abuse are to be found in the central nervous system. Out of his sex-egoism and false conception of manliness, the mind of the youth turns naturally to the cigarette for experimentation and exploitation—justifying himself in part by the fact that the individual cigarette contains but a small amount of tobacco. His growing and impressionable nerve centers react powerfully to the toxemia and soon come to demand its sustaining and soporific influence. Not only is there soon acquired the tobacco habit, but curiously there arises in not a few cases loss of inhibitory, moral control. Among high school students I have observed not rarely in those who are cigarette smokers a loss of mental acuteness but more conspicuous still a weakening of moral stamina—the evil fruitage of tobacco excess. Hand in hand with this failure is apt to arise an overweening sex egoism, often with shocking tendency to sexual eroticism and degeneracy. Not a few lads have I known of ideal heredity, with every advantage of home training and education, well endowed, who have started down the immoral toboggan with cigarette smoking.

Follow an individual of this type, or the older, hardened "cigarette fiend" through a grave, acute or chronic infection. Note the saffron-tinted fingers, the tremorous hand, the nauseous, sweetish odor which permeates the room, and

the imperative and constant demand of such a patient for more cigarettes, and deny if you dare the heightened gravity of prognosis—made so by his habit. Is it not incumbent upon the profession at this time to more frequently call attention to the ominous significance of these things?

Very recently cigarette smoking has developed a new phase of great seriousness in my judgment. More as a matter of fashion than as part of woman's enlarged liberty of rights and conduct, smoking is becoming quite the thing among the "smart set". And now like other fashions it is insidiously but surely extending to all social classes. Upon three different occasions within recent months I have seen neatly dressed girls in their teens, seated in public places with their parents, brothers, sisters and sweethearts, smoking cigarettes. Is the fashion to become universal without the profession of medicine raising a finger to point out the dangers? The generally recognized emotional instability of the female sex indicates a type of nervous constitution in which chronic cigarette toxemia is more likely to act with disastrous results than in men. Young women, therefore, who acquire the habit are likely to manifest even more frequently than men, loss of intellectual acuteness, a weakening of moral sense, and impaired general nutrition. Loss in beauty will necessarily accompany the impaired physical, mental and moral tonus.

Were I asked the most common habit of our modern civilization, I should answer without hesitancy, chronic constipation. The "American Army of Constipation" is made up almost entirely of women. It is one of the physical vices begotten of wealth, luxury, ease and physical indolence. Our pioneer mothers were not so generally afflicted. The habit is less common among European than American women, because more of them perform manual labor which calls into action the general muscular system—notably the muscles of the abdomen. Women of the English middle classes engage quite generally in open-air recreation which combats the tendency to chronic constipation. Americans are more prone to the condition because of social habits and customs. Coarse foodstuffs which offer bulk for the bowel to labor with are tabooed in good society as vulgar and common. Instead knick-knacks and delicacies which pamper the appetite and weaken intestinal effort are cultivated. The bowel muscle like other unused musculature becomes soft. Thus insufficient or improper food residue within the lower bowel, indolent habits of body or improper exercise, and failure to observe the habit of regularity in responding to bowel stimuli, result in constipation. Recourse is had to artificial measures acting directly or indirectly upon the defecation center. A purge, a saline, a laxative is called upon to do what proper physiological management, from day to day, should have accomplished. More and more the individual comes to depend upon artificial help. Although primarily a hygienic and dietetic abuse, it becomes ultimately and chiefly a cord change. The defecation reflex takes on a plan of action which calls regularly for its stimulus. A horse trained to go by the whip will not hasten his lazy pace until goaded. So the cord center in chronic constipation comes to demand its accustomed stimulus before getting into action.

Contributing very largely to the almost universal habit of constipation amongst women are the quacks and mercenary minded of the profession—appealing to the public through "cascareens", "Aloettes", "Nature Remedies" and the like. Nor should we in this connection fail to acknowledge our own responsibility. Too often we yield to the layman's demand for a remedy pursuing the easier if the lazier course of prescribing cascara, an aloin compound or other laxative. The larger duty in such cases is to lay down with emphasis the physiological law, of proper exercise and diet. It is for us to inculcate publicly and privately, that instead of chiropractic titillation of the spinal nerves, osteopathic pummeling of the abdominal muscles and bowel, or the repeated use of laxatives, real, fundamental and lasting progress is made toward a healthful bowel condition, by living the physical, hygienic and dietetic life which will make these measures unnecessary. Is this not a phase of public health in which large responsibility is placed upon the profession? Are we seizing the opportunity and discharging the duty—publicly as well as privately?

Does it not lie within our power to arouse in the feminine world a larger interest in open-air activities—tennis and golf for those who can afford it; hiking and nature study for a large number; floral and vegetable gardening for those who have the facilities—and there are many such; rowing, riding, swimming, athletics, etc.; and last but most important of all, actual participation in the science, art and labor of domestic life. The false conception of modern social life that a "lady" should not work with her hands is pernicious in principle—harmful alike to health and happiness. It would be well for every woman of the day to read Gene Stratton Porter's novel, "Her Father's Daughter," for its wholesome suggestiveness to mind, soul and body. Work, mental and physical, should enter into the program of every life. Not only does it give the satisfying consciousness of duty performed; it yields a return in a more healthful body functioning without artificial aid.

REMOVAL OF TONSILS AND TEETH FOR CURE OF RHEUMATISM

Statistics show that there has been a very marked decline in the mortality from acute rheumatism during the last ten years. In a statement concerning this matter, the Metropolitan Life Insurance Company quotes a leading clinician to the effect that the chief causative factor of acute rheumatism is a focus of infection within the body and usually within the head, chiefly within the mouth and throat, and the reduction in the death rate in acute rheumatism is due to the removal of these foci. The tonsils are the chief sites of infection within the head which are accessible for easy removal. Incidentally it may be stated that the number of damaged hearts is lessening as a direct result of the removal of such foci of infection as diseased tonsils and teeth.

However, it is a question if this intensive attention to mouth hygiene and the attempt to remove all foci of infection by extracting teeth and removing tonsils is not going to the extreme. There can be no question of doubt about the part played by foci of infection in any part of the body in producing rheumatism and cardiovascular as well as renal disturbances, but just at the present time it seems the fad, for those physicians who are rather superficial in their study of cases, to pounce upon tonsils or teeth as a causative factor in a large number of diseased conditions that may be due to some foci of infection in other portions of the body. Many inoffensive tonsils and comparatively sound teeth have been sacrificed in consequence of carrying a very valuable and justifiable procedure to extremes. Perhaps dentists have been most at fault, though for the most part they have been encouraged by the members of the medical profession who have insisted that foci of infection about the roots of teeth, with their possibilities of great harm, should be removed, and no doubt this has led many dentists to over-estimate the danger connected with unsound teeth that rational judgment would commend to treatment. The loss of teeth is a serious thing to the average individual, and the recommendation to sacrifice teeth should be given only after a most thorough and analytical examination, not omitting an x-ray examination by a skilled and experienced roentgenologist. The sacrifice of tonsils, when the operation has been done skillfully, is not such a serious matter, even when inoffensive tonsils have been removed, but here again the recommendation to have tonsils removed should be based upon findings which justify operative procedures. A tonsil which some clinicians have termed "juicy" and from which mucopurulent secretion may be expressed, is potentially a source of trouble, *no matter what its size.* On the other hand, tonsils which may be termed "enlarged" but which are and have been free from inflammation, and from which no infective material can be expressed, may be considered reasonably healthy and in no sense a focus of infection.

In an examination of the tonsils mere inspection does not suffice, but the organ should be drawn from its bed by fixation forceps for the purpose of noting its freedom, and it should be squeezed for the purpose of determining whether it contains infective material. Having decided that the tonsils are infected and should be removed, the operation should be done in a skillful manner by one who has had training and experience in that particular work. Bad tonsil surgery is putting the procedure into as much ill repute as bad judgment in deciding when the tonsils should be removed. The whole subject is one for the careful consideration of clinicians, and if we are going to keep it on a rational basis we must use that intelligence which is due every scientific problem if it is to be handled in a sane manner. The lowering of the morbidity statistics as a direct result of removing foci of infection from the body which, in a large portion of cases means ablation of tonsils and improvement of the hygiene of the oral cavity, is deserving of credit to the medical profession, but we ought to be guarded in our endeavors in this direction if we are to prevent our procedures from getting into disrepute through our failure to consider the case from a rational standpoint.

DR. HUGH CABOT'S SOCIALISTIC SCHEMES

DR. CABOT'S REPLY AND OUR ANSWER

In the last or October number of THE JOURNAL we printed an editorial entitled "Dr. Hugh Cabot's Medical Socialistic Schemes for Michigan", with allegations and comments which we believed based upon suitable foundation. To this editorial Dr. Cabot has taken exception, and his reply to the editorial, together with our answer to the reply, are herewith reproduced and are self-explanatory.

November 7, 1921.

EDITOR OF THE JOURNAL OF THE
INDIANA STATE MEDICAL ASSOCIATION,
406 West Berry St., Fort Wayne, Indiana.

My Dear Sir:

Your editorial in the number of October 15th has been brought to my attention. Your reading of a newspaper quotation in which I am alleged to have said certain things is so diametrically opposed to the facts that I make haste to write you on the matter. You have apparently concluded from the newspaper paragraph which I do not recognize, that I am at some time supposed to have advised the admission to the University Hospital of patients who could afford to pay. Now this is precisely the reverse of the position which I have always taken and now take in the matter. The only alteration which has been made in the admission of patients to the University Hospital since my coming here two years ago has been the ruling that patients who can afford to pay a fee shall always be required to do so. I am quite of your opinion that it is improper to use the money of the State for gratuitous service to people not entitled to it and this opinion I have long held and expect to continue to hold. If the University Hospital were to admit patients who could afford to pay, I should be wholly of your opinion. As it does not and as every precaution is taken to avoid this form of pauperism, it appears to me that the criticisms you level at me are not well taken.

My opinions in regard to State Medicine to which you also refer are quite the reverse of those with which you credit me. I have always been opposed to it and my published statements on the subject might readily be obtained. I would refer you to my paper entitled "Compulsory Health Insurance, State Medicine or What?" delivered as the Annual Discourse before the Massachusetts Medical Society, June 9, 1920, at the end of my first year as Professor of Surgery at Michigan. I enclose a copy of the paper in order that you may see that I was at that time violently opposed to State Medicine. I would also refer you to my address at the opening of the Medical School this year which may be found in the November number of the *Journal of the Michigan State Medical Society*. From this, you will appreciate that my opinions have not altered in such a way as to become more favorable to State Medicine and I therefore think that in some way you must have been misinformed in regard to this.

I assume that you would not willingly do injustice to a colleague and therefore I assume that your willingness to condemn and censure me on opinions that I have never held and do not expect to hold is due to misunderstanding. I do not know that this is the proper place to refer to your strictures aimed at me concerning "soft berths", but without going into what may be regarded as a personal question, it is perhaps proper to point out that those looking for "soft berths" do not do so by accepting positions that cut their incomes more than in two. I do not make any claim to credit because I have seen fit to reduce my income by a large amount, but I do think that it entitled me to be free from the assumption that I am looking after my own comfort in doing so. Considering the rather severe way which you have written concerning me, I would ask that you give this at least as much publicity as you have given your editorial.

Yours very truly,
HUGH CABOT, Dean.

November 10, 1921.

HUGH CABOT, M.D.,
Medical Department, University of Michigan,
Ann Arbor, Michigan.

My Dear Dr. Cabot:

Your letter of November 7, taking exception to an editorial in the October number of THE JOURNAL, has been received and noted.

I have not the slightest intention nor desire to misrepresent or misquote you or anyone else, and I am just as much in favor of those things which make for medical progress as you are. Perusal of numerous newspaper clippings covering some of your speeches, and talks with various Michigan medical men who thought they rightly interpreted your attitude, have led me to believe that you favor various schemes which many of us believe not to be to the best interest of the public or the medical profession at large. From conversations with medical men in other states it would seem that I am not the only one holding such opinion. You may have been misrepresented, and perhaps the unfavorable opinion is based upon a wrong interpretation of what you have said and what you have been doing.

You are now the head of a great medical school that, I do not think you will deny, has been guilty—certainly until very recently—of a very loose method of determining who is entitled to gratuitous services at the hands of its Hospital Staff. While I do not think that the pecuniary phase of the question, so far as it affects medical men not connected with your institution, should be overlooked wholly, yet there are broader considerations which justify me in believing that the practice carried on by your Hospital and its Staff, in the final analysis, is detrimental to the public as well as to the medical profession. Knowing that this practice exists, are medical men not justified in interpreting the statement of the Dean of this institution as indicating that the practice is to continue when you say, as you were reported in the Detroit Free Press, and which I notice you do not deny, that "rich and poor should be treated alike"? This statement is reported as having been made by you in connection with a discussion of the subject of admission of patients to the University Hospital.

I had not the pleasure of seeing your paper published in the *Boston Medical and Surgical Journal* until I received a reprint of it from you, and today I have received the November number of *The Journal of the Michigan State Medical Society*, containing your address delivered at the very recent opening of your Medical School. In the latter you acknowledge that there has been misapprehension in the minds of the physicians concerning the attitude of the faculty of your institution, and this necessarily must indicate that there has been occasion for much misapprehension.

Neither you nor any member of the faculty can justly deny that the Medical Department of the University of Michigan has done more to pauperize the community by granting gratuitous medical and surgical treatment to the well-to-do than any one institution or factor in the Middle West. In fact the action has been so flagrant that it has been a common remark among Michigan doctors, as well as doctors in some contiguous states, that it is exceedingly difficult to secure even a very ordinary fee from many well-to-do people for the reason that those people claim that they can go to Ann Arbor and have their work done for nothing, with the hospital charges as their only expense. Furthermore, such practice on the part of your University helps to make it impossible to secure decent remuneration from

the rich industrial organizations or insurance companies for any medical or surgical services rendered, and I do not think that anyone will admit that those organizations should be an object of charity at the hands of the medical profession or even the State.

So far as I know, not a single person has objected to the admission of well-to-do or very wealthy patients to the University Hospital or the Medical School clinics, providing they pay respectable fees for the services, but objection is raised to giving these patients *gratuitous* services, or services at a very nominal fee. The practice followed by your institution is wrong in principle, and in the end is bound to end disastrously. In the discussion of this matter we may overlook the unfair competition of the University, with its injurious effects upon the private practitioner.

Primarily, your University Hospital was established as a teaching hospital, and as such it not only fills a great need but has received a sufficient number of patients for teaching purposes and has furnished skilled gratuitous services to many deserving poor. If for any reason you fear that there will be a dearth of material it seems to me that it would be possible to secure all the cases necessary, and even more than your institution can care for, by appealing directly to the medical men of Michigan to send you one or two cases each throughout the year as you already have suggested in an indirect way. It should be understood that these cases come from the deserving poor, and if others are referred to the University Hospital such cases will be required to pay fees consistent with ability to pay.

Now that you say so, over your own signature, I am willing to believe that you are opposed to the very practices that have made the Michigan University the subject of bitter criticism, and it is unfortunate that you, in your choice of words, have had your real attitude misinterpreted. Knowing what the Hospital of the University of Michigan has been doing, and then have you openly say that "rich and poor should be treated alike" when they enter the University Hospital, makes it appear that you are sanctioning a continuance of the policy that heretofore has existed. It appears that what you wanted to say is that so far as being admitted to the Hospital is concerned, anyone can be admitted, but all are *not* treated alike so far as paying for the services is concerned. If the Hospital of your institution now is charging well-to-do patients fees consistent with their financial circumstances, which seems to be a recent innovation, then that fact should be made known to the medical profession to the end that the justifiable criticism formerly aimed at the Hospital shall cease and deserved cooperation be given you and your confreres on the Staff.

Concerning my reference to the "soft berth" perhaps that is taken in a manner not intended. I knew that you gave up a private practice that netted you more money than you will get out of your present position, though I think you will agree that being the head of a great University, with a fixed salary that enables one to live more than comfortably, is in the minds of many sufficient to counter-balance any loss sustained in giving up private practice. But what about the poor though competent doctor who doesn't have such a position and has his income from private practice unnecessarily and unfairly reduced in consequence of the competition of the University which brings about this discussion?

The term "State Medicine" has been applied rather loosely, but I think it generally is conceded now that by State Medicine is meant providing medical and surgical attention by the State to all who desire it, and this in the end means wiping out private practice wholly, or at least to a very large extent. Your scheme for furnishing "community medical and surgical service" by the members of the Staff of your institution and a selected few outsiders, if I understand it correctly, is a step in the direction of State Medicine in that it paves the way for the operation of a more comprehensive plan directly under the control of the State. Aside from this it starts out by creating a sort of caste in the medical profession, known to the public as such, which is bound to create dissensions and produce vicious results.

I am in favor of everything which tends to improve public health conditions and ameliorate the sufferings of the sick and disabled, but I am opposed to all practices, under whatever guise, that tend to pauperize the community, to stifle individual initiative in medical practice, and unjustly trample upon the rights and privileges of individual members of the medical profession. Hospitals, whether federal, state or municipal, should be open to people, irrespective of social position, but the medical and surgical services should be gratuitous only to the worthy poor, and charged for to all others consistent with their ability to pay. The record of your University Hospital, and your statements which you now say have been misconstrued, are not in keeping with the plan mentioned, and that is the reason for the criticism to which you take exception. The medical men of Michigan have certain inalienable rights, and one of them is the right to practice medicine without the unfair and unjust interference with their efforts to earn an honest livelihood. The University of Michigan has trampled upon this latter mentioned right in not only a ruthless manner but in a manner which true economists believe to be detrimental to the public weal.

I believe that I am safe in saying that practically all of the visionary but impractical if not wholly vicious schemes which tend toward the socializing of medicine owe their origin to medical men, erstwhile leaders in the medical profession, rather than to any lay person or lay organization. It is the so-called leaders, like yourself, who start innovations, sometimes with good intentions but more often with selfish ends of one kind or another in view. Not infrequently the innovations are not for the best interests of all concerned and at such times criticism and opposition is justified. I hope the day has arrived when every right thinking doctor in Michigan, through his voice as well as his vote, will register his opposition to the various schemes for socializing medicine, and that will mean offering vigorous protests to some of the plans that some of us believe you have sanctioned and supported.

Concerning this matter of criticizing the sponsors of detrimental innovations as they affect the medical profession, permit me to quote from a letter to me, commenting upon the editorial to which you take exception, as follows: "There is no position in America so high but that its occupant can be criticized for his words and actions. It has become the habit in America to consider the so-called leaders of the medical profession as immune from criticism by their professional brethren—let us change that habit!"

Very truly yours,

ALBERT E. BULSON, JR.,

Editor of THE JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION.

P. S.:—In accordance with your request your letter, together with this reply, will be given as much prominence in THE JOURNAL as was given the editorial to which exception is taken.

THE NURSING PROBLEM

A late number of the *Pictorial Review* contains an attack upon the nursing autocracy, by Dr. Charles H. Mayo, in which he offers deserved criticism of the autocratic practice of the majority of the trained nurses in demanding seven to ten dollars a day for services, insisting upon short and regular hours, and in all too frequent instances exhibiting too little of the milk of human kindness in the performance of their duties. He calls attention to the fact that in the vast majority of cases a highly trained nurse is not necessary, and points to the conclusion we already have reached that an advanced standard of preliminary education is unnecessary in order to make a good practical nurse, and that the last two years of a nurse's training is largely superfluous and benefits the hospital most.

While Dr. Mayo very justly contends that there always will be room for the highly trained nurse in specially selected cases, and she always will be in demand by the wealthier classes, yet for the great majority of cases not only is a less highly trained nurse eminently satisfactory but the lower fees of a less highly trained nurse are absolutely necessary for the average run of patients. For people in moderate circumstances, which make up the bulk of our population, the exactions of the modern trained nurse prohibit her employment. As a solution to the problem Dr. Mayo suggests the training of 100,000 girls for sub-nurses. In reality this means accepting girls of ordinary intelligence, not necessarily high school graduates or possessing one or two years of college or university training, and turning them out as practical nurses after a few months' intensive training. It always has been our contention that there is a great field of usefulness for such practical nurses, and that, except in rare instances, the highly trained and specialized nurse, usually unsympathetic and autocratic in her determination to stick to a fixed program as to the kind and quality of work she will do, the number of hours she will work and the pay she is to receive, is superfluous, and a luxury (?) which few can afford and in reality which few care to tolerate except through necessity of having someone to care for the sick.

No doubt Dr. Mayo, who handles the whole subject in an analytical way and offers a solution for the problem, will come in for a good deal of criticism, but nevertheless the discussion of the subject is entirely rational and deserving of thoughtful consideration.

MEDICAL SUPPORT FOR PLAYGROUNDS

In these days of industrial depression more than ever there is need for enthusiastic support from the medical profession for the playground movement in most Indiana cities. In this, as in most questions of preventive medicine, the public is willing to leave the initiative to the doctors, while we as a class are apt to forget the tremendous influence of outdoor exercise upon the future health of our boys and girls because we are "too busy". Credit is due to the few doctors who have found time to interest themselves in behalf of the children along this line, but they are so few in comparison to the number that should obtain as to be almost a negligible factor.

For many years Indiana has boasted of her educational system, but as a matter of fact there is only one city in the whole state that has attacked the school recreation movement in a thoroughly modern fashion, that city being Gary, with its playgrounds of twenty acres or more on each school premise. She not only has the playgrounds, but she puts them to use all day long, in the evenings, on Saturdays, and a part of Sunday. The parents are encouraged to use them in the evenings, either with or without their children, and teachers are trained in organized play in order that the grounds be under competent supervision continuously during operation. For such training in play-supervision teachers are allowed extra salary, with full-time pay throughout the summer. While the Gary school-day is considerably longer than in the average city, yet a two-hour recreation period is made a part of the compulsory curriculum, a feature which of course is entirely unobjectionable to the pupil. The rewards for this intensive training, both physical and mental, have come in the shape of good, robust students who are not only finishing their high school course at fifteen or sixteen but are also sufficiently advanced as to receive credit of from one to two years in any of the standard universities. Contrast these conditions with those that obtain in most Indiana cities wherein a maximum of thirty minutes per day is allowed for recreation on a school yard that usually has the "standing room only" sign out during recess.

When it is recalled that in the recent war over one-fourth of all the recruits examined for the American army were found physically unfit for service, that from six thousand to seven thousand school children of the United States are annually claimed by tuberculosis, and that the average maturity expectancy of the American newly born is only fifty per cent, the urgency of the appeal would seem established. The situation is quite analogous to the more or less familiar tadpole experiment wherein the growth of the individual was exactly proportionate to the size of glass receptacle in which he was domiciled.

Joseph Lee expresses the thought that play is natural not only because it originates in orig-

inal nature, but because it conforms at every moment of the child's life to the genetics of his growth and development. It reflects the neuromuscular co-ordinations established at the time and establishes those that are ready to be formed. It reflects also the various instinctive tendencies (or many of them) as they ripen, and helps to ripen and strengthen them. In short it obeys the self-finding and self-developing push within the child. It also respects the limitations of the child as regards these neuromuscular co-ordinations and psychic motives. Play is childhood's heritage, and the one means by which it can attain its full heritage of symmetry, normality and health of body and mind. Real work is the fulfillment of the great play instincts, in fact it is the highest form of play. All pursuits that justify themselves are play, and work is the function of the great team instinct that is the fulfillment by us in our individual capacity, of the law of the social whole.

In one of his campaign speeches, President Harding once spoke as follows: "I regard play as having no small part in the building of citizenship. I am glad to make a campaign speech about play. Competition in play teaches the square deal. I am making no appeal in this campaign that I will not be willing to have tested by the standards that good competitive sport has set up in all ages and among all men. I want only those behind me who are willing to play the game. We have had too much encouragement given to the men who wanted to cut second base or get something for nothing."

The school playground movement then makes not only for good sportsmanship and hence better citizenship, but for broader and saner physical development for the many rather than the specialized intensive training for the few star athletes who comprise the teams of the more strenuous, competitive athletics and whose hearts become sufficiently dilated as to make them easy victims to any severe infection.

Let the members of our profession lend their support and influence toward establishing bigger, better school playgrounds that may work at full-time efficiency for the greater development of the school children of Indiana.

QUALITY NOT QUANTITY WHEN INCREASING THE MEMBERSHIP IN OUR MEDICAL ORGANIZATIONS

We have been wondering if the American College of Surgeons eventually will not drift into the position of taking in most anyone who has sufficient "pull" of one kind or another to get into the organization without possessing the requirements prescribed. It may be difficult to keep all undesirables out of an organization, but there is no need of encouraging laxness in the consideration of credentials. There are some secret orders to which at one time it was an honor to belong. However, at the present time, when we attend some of the meetings of these secret orders and have not one but several scoundrels walk up and offer the right hand of fellowship and try the "brother" act on us, we are quite undecided as to the value of affiliation with such organizations. A few years ago the American Medical Association sent Dr. J. N. McCormick, of Kentucky, all over this country preaching the doctrine of medical organization and the advisability of admitting practically every licensed physician to the ranks of our regular medical societies. The plea was made that we should take the "off-color" doctors into our medical societies in order to reform them. We took Dr. McCormick at his word and went out into the highways and byways hunting for licensed practitioners to swell the ranks of our local medical societies, and the result has been that we have not reformed the "off-color" members of our profession nor have we improved the character of our medical societies. In reality what we have done is to help establish a dominating crowd in many of our local societies that takes a special delight in voting down any worthy object that comes up for consideration. Whenever a question of ethical importance, or for that matter, almost any question that has the approval of right thinking doctors, is up for consideration, the "off-color" doctors flock to the meetings in droves for the purpose of defeating it. The rest of the year they are conspicuous by their absence, for a scientific meeting is of no interest to them. The American College of Surgeons started out with high aims, but there seems to be a disposition on the part of many of those who belong to the organization to encourage a combing of the field for members, and it is even hinted that the committee on credentials should be lenient. It is very evident that leniency has been shown in many states if all reports are true and we can judge the qualifications of members by their acts.

For years THE JOURNAL has been preaching "quality, not quantity" as a guide in securing members for our medical societies. We have no faith in the proposition that we ought to take in members in order to reform them. A man who is fundamentally right in the beginning remains so, and whenever he starts out on the wrong foot he generally continues to be on the wrong foot throughout his entire career. He may have spasms of goodness, but he generally reverts to the path that is perfectly natural for him to trod. You "can't get blood out of a turnip," and you can't get righteousness out of a doctor who is naturally, in some manner, unclean or unworthy of the right hand of fellowship of respectable members of the medical profession. A man may be incompe-

tent, but he can correct his deficiencies and he should do so before his qualifications receive the stamp of approval. In our humble judgment medical organizations should scan more closely the credentials of those who apply for membership, and this is especially true as concerns those applicants about whom there is a suspicion as to moral integrity.

VALUE OF RADIUM IN THE TREATMENT OF CANCER

At the recent session of the American College of Surgeons, at Philadelphia, the well-known surgeon, Dr. John B. Deaver declared, in an address before the College, that radium had failed in curing cancer in any stage, and in fact he doubted if radium produced *any* beneficial effect. This edict, coming from a man of the skill and experience of Dr. Deaver, created much surprise and comment, ending in a decision of the College to have the matter thoroughly investigated by a committee that was appointed for the purpose. It is unfortunate that a discussion of the subject appeared in the public press, with considerable criticism of the medical profession for having exaggerated the value of radium. It may be that radium is not proving as valuable in the treatment of cancer as some have believed, and yet it will take more than the conclusion of one man, no matter how eminent, to change the opinion of many serious workers and hundreds of cured patients that radium offers much hope of greatly relieving if not absolutely curing many cases of cancer. However, time and accumulated experience will tell the story, and in enabling us to arrive at dependable conclusions an investigating committee such as contemplated by the action of the College of Surgeons will be approved.

LOWERING THE IDEALS OF THE AMERICAN COLLEGE OF SURGEONS

If the American College of Surgeons stands for anything worth while it will not only purge its membership of undesirables but it will demand of its members a stricter adherence to those principles and objects which not only received the approval of right thinking men when the organization was conceived, but which in reality led the same men to become identified with it. We have heard it stated repeatedly, and from appearances with good foundation, that the iniquitous practice of "fee splitting" still continues in various forms by certain men occupying more or less prominent positions in the College. Our contention is that there should be not even a suspicion of wrongdoing in the fee splitting line among those who have obligated themselves morally to abstain from the practice and to strenuously object to it in others. There certainly should be an effort put forth to establish the status of any man under suspicion, and if guilt be discovered then punishment should be swift and sure. The College owes it to itself to do this, and no amount of influence should hamper the work or lead to a camouflage of the findings. What pertains to the practice of fee splitting also pertains to the unsurgical and even criminal methods employed by some noted surgeons in making a surgical operation the excuse for the performance of an abortion, or, permit us charitably to say, making an unnecessary abortion secondary to other surgical treatment.

In no field of human endeavor is an active conscience more necessary than in the practice of surgery in any of its various forms, and that applies equally to the application of the science and to the economic or pecuniary phase of the work. The American College of Surgeons started out with high ideals and is destined to perform a wonderful work in improving the status of medicine and surgery as affecting both the medical profession and the public. The College will fail to perform its function if it deviates a hair's breadth from the plans conceived and adopted as a creed. It can well afford—yes, it is even a duty—to have a day of reckoning occasionally, an inventory so to speak, in determining whether laxness is permitted in living up to the tenets of the organization.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

IT is time to separate the sheep from the goats in this scheme to socialize the practice of medicine. We should quit paying homage to erstwhile leaders who would destroy the medical profession and all its traditions.

FROM all reports much may be expected from toxin-antitoxin injection in the production of permanent immunity to diphtheria. As has been pointed out by the recommendations of the Indiana State Board of Health, all children entering school for the first time should be immunized at once. Susceptibility to the disease may be determined by the Schick test.

BEFORE now we have stated that the hardest fight before us, as medical men, is the fight against some of the erstwhile leaders in our medical profession if we are to preserve the medical profession and its traditions. The attitude of Johns Hopkins University, and the University of Michigan is ample evidence of our contention. Before long it will be a fight to the finish, if annihilation of private medical practice is to be prevented.

SOME of our advertisers are testing out their advertising by offering to furnish free samples of perfectly trustworthy preparations of their manufacture, and we are wondering how many members of the Association will take advantage of the offers. Incidentally we desire to call attention again to the importance of letting advertisers in THE JOURNAL know that you patronize them. It helps the advertisers, it helps us, and, lastly, helps you, for without advertising we could not publish THE JOURNAL.

THE Christian Scientists ought to be in great glee, for a California court has decided that "in the state of California prayer is a lawful means of healing disease". This decision was made following a trial of a Christian Scientist for manslaughter in the case of a child dying from diphtheria, with no other treatment than prayer. If this goes on it will not be long before it will be possible to commit most any sort of a crime and go unpunished if the claim is made that the manner of producing death is a method of treatment.

IF public health officers desire to secure endorsement and support for their work from the regular medical profession there will have to be a little change in their attitude concerning the socialistic schemes which various public health officials are supporting at the present time. We are not going to permit the socializing of medicine if we can help it, and the time is ripe for offering opposition to the support which some of our public health officers and other misguided leaders in our medical profession are giving to some socialistic schemes.

THE Roycrofters constantly are soliciting doctors to subscribe for their periodicals, but considering the off-color of the editorial comments pertaining to scientific medicine, which not infrequently appear in the periodicals made notorious by the late Elbert Hubbard, and considering that any and all kinds of advertising—even chiropractic stuff—appears in this periodical, we hardly see how intelligent and progressive members of the regular medical profession can subscribe for anything put out by The Roycrofters.

ON the twenty-fifth anniversary of *The Laryngoscope* the editor publishes a note of appreciation in which he makes some very pertinent remarks concerning the work of the editor. A long experience in the editorial game prompts us to appreciate the force of one of his paragraphs, and to reproduce it. It is as follows:

> The path of editorial conduct and business management of a medical journal is neither smooth nor strewn with roses. Personal differences, editorial jealousies and contentions, medical politics, financial stringencies, contributors' eccentricities, ethical exactitudes and many other handicaps must be met in dignified and decisive manner, and an editorial management that can run this gauntlet successfully must exhibit strength of convictions and faithfulness to ideals.

THE surgeons are losing out. No longer can Crile, the Mayos and our own excellent Indiana surgeons operate goitres without fear of offending the real wise heads in the goitre curing game, for the chiropracs, according to their advertising, claim that they are curing goitre by "adjustments". A lot of women who were invalids and nervous wrecks before submitting to a thyroid operation by competent surgeons must feel a sense of humiliation to think what dupes they were to have submitted to the knife when a few manipulations of their goitres or other parts of their anatomies would have produced the same results!

IT is reported that the Post Master General has issued an order to the effect that post masters must be in their offices eight hours a day and not absent themselves therefrom longer than one-half hour on weekdays without special permission. It is very evident that someone has been getting on to the fact that most post masters in the larger towns and cities are mere figureheads, that the real work is done by the office help, and oftentimes the morale is sadly deficient as a result of the easy going methods of the chief. There is certainly room for great improvement in most federal offices and the post office department is no exception.

POLIOMYELITIS is on the increase, there being many more cases in 1920 than during the previous year, and this year the number of cases is even still greater. The peculiar feature about the disease is that it appears in isolated cases and does not show any tendency to occur as an epidemic. The majority of the cases are in children, though there is a good percentage of

cases occurring in adults. Paralyses are, in most instances, not severe. The increased prevalence of the disease seems to indicate greater precaution on the part of health authorities in discovering unreported or unrecognized cases and in taking all precautions to avoid an epidemic of serious consequences.

THE bacteriological laboratory of the Indiana State Board of Health makes many examinations during the course of the year and so far as we know no fees are collected for the services. As a matter of fact there is no reason why a fee should not be charged in those instances where the patient is able to pay a fee. In reality the well-to-do should pay for their laboratory work just as they pay for anything else. There is no reason why the State should help to pauperize the community by doing free laboratory work for any who may ask it, to say nothing of entering into competition with hundreds of men who are doing laboratory work as all or a part of the vocation and from which they are making a living.

FOR the benefit of the large number of State Journals that exchange with us we desire to call attention to the necessity of determining where the delegates to the A. M. A. stand on many questions of vital interest to the welfare of the medical profession at large. We have had examples of what some of the leaders in the profession would do to us if they have their way. It is time to know something about the attitude of those whom we send to represent us at the great parent organization which supposedly represents the voice of a very large majority of the medical men in this country. The trouble of it is we sometimes are betrayed, and if necessary, in order to have our wishes respected, our delegates ought to go instructed.

To those authors who may desire reprints of their papers as they appear in THE JOURNAL, we desire to say that the management has nothing to do with the reprint proposition except to employ printers possessing reputation and facilities justifying the opinion that they will take care of the matter in a satisfactory manner. The printers have made a rule to which no reasonable doctor can take exception, to the effect that check in advance must cover cost of any and all reprints. This is no reflection upon the financial credit of any author, but is necessary in order to avoid the annoyance and expense of determining credits and carrying many unnecessary small accounts. All orders for reprints must accompany the corrected proof returned by authors.

A WELL known advertising firm has sent out to many physicians a questionnaire asking about the medicinal value of raisins. It frankly admitted that the information is to be used in helping to advertise the raisins raised and marketed by growers of California. No stamped envelope is inclosed with the request, which shows the "nerve" of some of the advertising agencies in expecting to get something for nothing. Perhaps there will be many physicians who will be silly enough to answer the questionnaire, and it is barely possible that a few physicians who are mentally warped will give raisins the credit of being good for everything from tuberculosis to ingrowing toenail. However, the scheme mentioned is a smooth way to get endorsement for anything that is to be marketed and which may require some endorsement in order to sell well.

AT present the United States has one doctor to 720 persons and Canada has one doctor to 1050 persons. Of course, this ratio is very much greater for the cities. In fact, all cities and towns in the United States have more doctors than are actually necessary, and the same thing is true in Canada. The country districts in both the United States and Canada are suffering for the want of medical service. Doctors, like the majority of people in other vocations, prefer the cities, and flock there even though remuneration is less than it would be in the towns and villages. One of the problems to be solved is how to get competent medical service to the sparsely settled communities. There ought to be enough medical men who like country life sufficiently, and with it a respectable income, to justify locating in the towns and villages for the practice of medicine.

FROM actual knowledge we know that a few of the members of our Association are giving credence to some of the specious claims of pharmaceutical houses concerning the virtues of some of the proprietary preparations of secret formula that have been openly condemned as worthless or nearly worthless by the Council on Pharmacy and Chemistry of the A. M. A. We suggest that doctors go a little slow in accepting the extravagant claims put forth by various pharmaceutical manufacturers concerning preparations that have not been tested and approved in a manner which all men can accept. Usually information may be obtained by referring to *New and Nonofficial Remedies,* and *Propaganda for Reform,* published by the A. M. A., or, in case such books are not available, a reliable answer may be obtained by addressing the Council on Pharmacy and Chemistry of the A. M. A., 535 North Dearborn Street, Chicago, Illinois.

THE nerve of some of the social uplifters is astonishing. Recently a doctor who donates considerable time and skill to the alleviation of the sick poor of one of Indiana's cities was asked for a money contribution by a female soliciting committee for the purpose of supplying medical attention to those of the city entitled to charity. When told that doctors contributed more of real money value to charity than any of the citizens following other vocations, and contributed liberally to other philanthropies as well, the aforesaid female soliciting committee thought the doctor was quite stingy, and they bolstered up their further request for a donation by saying that the services donated to the poor should not be placed on a contribution basis.

Of all of the abuses that members of the medical profession suffer from, that of furnishing gratuitous medical and surgical services to the sick poor is one of the worst, and for which little credit is given, but Lord deliver us from the female soliciting committees that operate without rhyme or reason!

As a species of imposition to which doctors are subjected an example is offered in the request from life insurance companies for detailed and technical information concerning the prospective policyholders who have been the patients of the doctors from whom information is solicited. These reports, requiring time and effort on the part of the doctor, are solicited on the ground that a favor is being shown the patron of the doctor, when in reality it is a favor to the insurance company, and is but another method of securing something for nothing, so commonly practiced by insurance companies when dealing with the medical profession. Of course, the great insurance companies are objects of charity, and they always can find enough "easy marks" in the medical profession to justify the attitude of driving sharp bargains for medical examinations or the procuring of any information that furthers their business interests. As one prominent insurance man said to the editor of THE JOURNAL, "You doctors are a lot of suckers to bite at the bait thrown out by insurance companies, but as long as you are willing to bite why shouldn't we take advantage of it and profit thereby, for we are not in business for our health or for sentimental reasons."

SOME of the officers and employees of our Federal government do not possess even mule sense, let alone good horse sense. An instance of this is the request on the part of a government auditor for a report and detailed description of each treatment given to a veteran entitled to gratuitous services on the part of the government. Inasmuch as the affection was an acute affair, subsided in the usual length of time under the recognized proper treatment for it, and a detailed description of the several treatments would be unnecessary as well as superfluous for the edification of anyone with anything more than half a brain, we fail to understand why Uncle Sam should retain in his employ an auditor who exhibits so little evidence of being worthy of a position of responsibility. The present administration promised reform in the way of removing incompetent office holders, and eliminating the idiotic red tape which surrounds so many government transactions. Up to the present time we have not seen very much evidence of reform, but we hope to see something of it before long, as there is great need for the discharge of a lot of brainless employees who not only hinder the efficient conduct of governmental affairs, but are an extravagant and useless expense to the taxpayers.

ONE of our correspondents complains about the increasing number of six weeks' specialists, and very appropriately remarks that they are about as dangerous as the chiropractors or members of any other pseudo-medical cult who try to do something without knowing how. However, in view of our difficulty in securing a legal standard of requirements for the practice of medicine, it is not surprising that we should have some difficulty in securing some recognized standard for the practice of the various specialties. The more ignorant the general practitioner, the more likely he is to assume responsibility for which he is illy fitted, and he does not hesitate to pose as a surgeon, or specialist of any kind, as long as the patient is willing to submit to his ministrations and the doctor can secure financial gain thereby. While admitting that the man who has had four years of medical training in any of our good medical schools is far more worthy of the confidence of the public than any of the members of the pseudo-medical cults who have little or no training concerning the methods of recognizing and treating disease conditions, yet we must admit that we need a little house-cleaning in our own profession in weeding out incompetents, or perhaps we ought to say in the preventing of incompetents from doing work for which they are not qualified by either experience or training.

THE article entitled "The Truth About Vivisection," by an animal lover, Ernest Harold Baynes, published in the July number of the *Woman's Home Companion*, should have wide distribution among lay persons who may have been influenced by the misleading, untrue and

vicious statements promulgated by the Anti-Vivisectionists. At the conclusion of the article Mr. Baynes says, "In this article I have sought to give facts and allow my readers to make their own deductions. I honestly believe that some of the people who are preparing literature against vivisection are either making statements which they know to be untrue and misleading, or are deliberately closing their minds to the truth in its larger aspect." After showing up the Anti-Vivisectionists in their true light as purveyors of falsehoods and in the distortion of evidence to further their own ends, Mr. Baynes says, "I would not present this case nor would the *Woman's Home Companion* publish it if we did not both believe that it is of the utmost importance to the human race, and to animals as well, that medicine and surgery be allowed to advance unhampered by ignorance, prejudice and sentimentality." Having been thoroughly exposed by a layman, who makes no statement without ample evidence to support it, the Anti-Vivisectionists, through one of their wild-eyed enthusiasts, attempt a retaliation by asking all Anti-Vivisectionists and lovers of animals to boycott the *Woman's Home Companion*. Enough said!

A CERTAIN New York oculist has been writing books and pamphlets, evidently for advertising purposes, in which he makes some very irrational and absurd statements concerning anatomy and physiology of the eye, as well as treatment of eye abnormalities. As might be expected several newspapers and lay periodicals, believing that the statements published emanated from a recognized authority, are publishing some of the erroneous views expressed, very naturally increasing the prestige and probably the financial income of the originator of the ideas. One of the wild tales commented upon by even such periodicals as *Leslie's* and the *Literary Digest* is the one which concerns the recognition of the liar by means of the retinoscope, due to the alleged fact that when a person tells an untruth an error of refraction (myopia) is produced "because it is impossible to state or imagine what is not true without an effort". On the same theory we might suppose that when a person tells an untruth, any of the other involuntary muscular actions could occur. The absurdity of saying that temporary myopia always is produced by an individual who is not telling the truth requires no attention at the hands of those who believe in the scientific soundness of any theory advanced before its acceptance. In fact, the physician who promulgated all of these wild theories that have received so much attention from lay periodicals has been considered "nutty" by probably all of the reputable ophthalmologists. It is unfortunate that he should be taken so seriously by the lay public.

REED & CARNRICK issue a little proprietary journal called *The Medical Pocket Quarterly* which, aside from its advertising pabulum, frequently publishes some editorial comments which not only contain good common sense but are worth pondering over by physicians. In the September number we find something that perhaps our readers may not have seen and which we herewith reproduce:

WHY?

Why does a lawyer get $10—without moving from his seat—for making out a lease that any trained stenographer can fill out in ten minutes, while a physician gets only $1 to $3 for diagnosing and prescribing for a patient's ills, the correction of which will keep him fit to earn thousands?

Why does a mechanical engineer get $50 to $250 for looking over a plant and telling a manufacturer where to place machinery so as to get out of it maximum efficiency, and a physician get 1/25 to 1/125th that sum for looking over a man and telling him how to get the maximum efficiency out of himself?

Why are attorneys able to collect their fees usually in advance and doctors two months to a year after service is rendered, if they ever get them at all?

Why do doctors give away $100,000,000 worth of free service a year in hospitals, clinics, home and office treatment, while other men give away nothing?

Why are butchers, bakers, grocers and milkmen without education, many hardly able to read or write, able to earn more money than thousands of physicians with education?

Why do legislatures concede to lawyers practically every request they make for laws increasing the emoluments and safeguarding the interest of their profession and refuse practically all requests for increasing the emoluments and protecting the interest of physicians engaged in public health work and otherwise?

Why do doctors have to work 14 to 18 hours a day, seven days a week, to earn the monetary rewards of mechanics and other lay workers, working only 8 hours a day, five days a week and half a day Saturday, with all holidays off?

Why is it that a doctor making an honest mistake in the treatment of a patient is sued for malpractice and often mulcted in heavy damages, while a lawyer making the same honest mistake in the trial and handling of a client's case is never sued and never obliged to pay a cent of damages?

Why is it that we have to pay larger premiums for indemnity insurance than rum sellers, manufacturers employing workers at hazardous tasks, and almost every other type of risk?

BECAUSE WE ARE CONSIDERED THE SOFTEST AND EASIEST CLASS ON EARTH ON WHICH TO IMPOSE AND THE VALUE OF THE SERVICE WE RENDER THE WORLD THE LEAST APPRECIATED

ISN'T IT TIME WE WOKE UP AND GOT ON OUR TOES—TIME WE BECAME MORE AGGRESSIVE FOR OUR RIGHTS?

DEATHS

J. A. SMITH, M.D., 83 years old, died at his home west of Brownsville, October 5.

SARAH EMMA PRESTON, wife of Dr. J. L. Preston, of Cloverdale, died July 21, 1921.

MRS. MARY E. ROBINSON, wife of G. M. Robinson, M. D., of Loogootee, died September 27, at her home.

J. W. ELLIOTT, M.D., died at his home in Linden, Indiana, September 27, at the age of 59 years. Dr. Elliott graduated from the Medical Department of the University of Louisville in 1897.

HELEN L. MURRAY, M.D., age 52 years, took her life at her home in South Bend, October 6, as a result of ill health. Dr. Murray was a graduate of the Indiana Medical College, School of Medicine of Purdue University, Indianapolis.

CHAMBERS M. LINDLEY, M.D., aged 89 years, died in the Methodist Hospital at Princeton, October 26. Dr. Lindley graduated from the Ohio College of Medicine, Cincinnati, in 1860, and was a member of the Gibson County Medical Society, the Indiana State Medical Association and the American Medical Association.

WILLIAM F. BATMAN, M.D., of Crawfordsville, died October 23, as a result of apoplexy, at the age of 63 years. Dr. Batman graduated from the Jefferson College of Medicine in 1880. He was a member of the Montgomery County Medical Society, the Indiana State Medical Association and the American Medical Association.

R. H. VAN CLEAVE, M.D., of Farmersburg, was struck by a train and instantly killed on October 15. He was 68 years of age. Dr. Van Cleave graduated from the Medical College of Evansville in 1879 and was a member of the Sullivan County Medical Society, the Indiana State Medical Association and the American Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in *The Journal of the Indiana State Medical Association*. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

DR. SAMUEL HARRELL, of Noblesville, has resumed his practice after a prolonged illness.

THE Eleventh District Medical Society held its regular meeting at Marion, Indiana, October 20.

REV. HENRY W. VITZ, superintendent of the Protestant Deaconess Hospital of Indianapolis, died October 16.

DR. RALPH EMERSON MCINDOO and Miss Phronsie Lucille Martin, both of Kokomo, were married October 15.

DR. E. S. FISHER, formerly of Markle, has removed to Bluffton where he will reside and practice medicine.

THE Tipton County Medical Society was entertained by Dr. and Mrs. John W. Cooper of Kempton, October 5.

DR. EMERSON BARNUM and Miss Pearl M. Coers, both of Manilla, Indiana, were married Thursday, October 6.

DR. VINCENT LAPENTA, of Indianapolis, has been appointed royal consular regent of Italy for the state of Indiana.

THE Whitley County Medical Society held a meeting at Columbia City, October 11. A paper was presented by Dr. E. V. Nolt.

DR. DALE C. WEIR has removed from Mongo, Indiana, to Three Rivers, Michigan, where he will take up the practice of medicine.

DR. HOMER C. GLOCK has been appointed as a member of the city board of health of Fort Wayne to succeed the late Dr. A. J. Kesler.

DR. J. W. BENHAM, of Columbus, will spend the winter in Chicago where he will take special work in eye, ear, nose and throat diseases.

THE training school of the St. Vincent's Hospital of Indianapolis held commencement exercises October 27, seventeen nurses receiving diplomas.

MISS JUNE GRAY, of Indianapolis, was elected president of the Indiana State Nurses' Association at the recent annual convention held in Indianapolis.

DR. G. L. REA has resigned his position as head of the public venereal clinic in Fort Wayne to take charge of a venereal clinic in Charlotte, North Carolina.

MRS. LUCIAN HARRIS, of Rising Sun, has been appointed a member of the board of trustees of the Southeastern Hospital for the Insane by Governor McCray.

DR. G. M. LASALLE, of Wabash, has resigned from the firm of Drs. Wilson, LaSalle and Whistler and will devote his time exclusively to the practice of surgery.

THE Randolph County Medical held its meeting at Winchester, October 10. Dr. C. E. Bodkin presented a paper on "Radium" and demonstrated the use of radium.

DR. CHARLES E. BARNETT, of Fort Wayne, was elected president of the Mississippi Valley Medical Association at the recent annual convention held in St. Louis.

THE Adams County Medical Society met Friday evening, September 24, at the home of Dr. C. P. Hinchman of Geneva. An address was given by Dr. Ben Beavers of Decatur.

THE regular monthly meeting of the Madison County Medical Society, held October 17, was addressed by Dr. Julius Hess, professor of children's diseases in Chicago University.

PROFESSOR SODDY, of Oxford University, took to London two grams of radium which England is to have the use of for fifteen years when it is to be returned to Czechoslovakia.

A BEQUEST of $200,000.00 has been left to the medical school of Harvard University by Hiram F. Mills of Hingham, Massachusetts, for use in scientific research for a remedy for cancer.

DR. BYRON N. LINGEMAN, formerly with Dr. J. H. Barnhill of Indianapolis, is now associated with Dr. H. E. Greene, Joel Block, Crawfordsville, with practice limited to ear, nose and throat.

DR. and MRS. BERNARD RAVDIN, of Evansville, left October 16 for a six weeks' trip to New York and Philadelphia where Dr. Ravdin will take special work in the diseases of the eye, ear, nose and throat.

DR. PAUL T. HURT won the golf tournament conducted by the Indiana State Medical Association at Highland links, Indianapolis, Wednesday, September 28. Forty physicians were entered from throughout the state.

DR. W. A. HOLLIS, of Hartford City, attended the annual session of the American Academy of Ophthalmology and Otolaryngology and the Clinical Congress of Surgeons at Philadelphia. He returned about the first of November.

DR. J. D. MCCANN, of Monticello, went to Chicago, October 22, where he attended the meeting of the Association of Pennsylvania Railway Surgeons, of which he is president, and the national meeting of the American Railway Surgeons.

DR. ALBERT E. BULSON, JR., spent the last two weeks of October in the East. While there he attended the annual session of the American Academy of Ophthalmology and Otolaryngology and the Clinical Congress of the American College of Surgeons in Philadelphia.

THE Eye Sight Conservation Council of America is a recently formed organization, with headquarters in New York City, which purposes to create a greater appreciation of the importance of the care of the eye. The council is supported by voluntary contributions.

DR. J. O. RITCHEY has been appointed superintendent of the city dispensary at Indianapolis to replace Robert E. Neff, who resigned. The Board of Public Health also appointed Dr. Philip H. Sheridan as district physician for the dispensary to succeed Dr. George Bowman, who resigned.

THE School of Hygiene of Johns Hopkins University will send an expedition in May, 1922, to study the problems of health among the Eskimos in Labrador. Dr. Victor E. Levine of the Creighton School of Medicine, Omaha, will go in advance for a preliminary survey of the climatic conditions.

THE DeKalb County Medical Society held a meeting at Garrett, October 13. A clinic was held at the Sacred Heart Hospital, and at the banquet, served by the Sisters, a paper was presented by Dr. House, his subject being "The Conscious and Sub-conscious Mind and Its Effect on the Physical Condition."

DRS. JAMES R. and JOHN W. NORREL, J. T. JOHNSON and S. H. J. DAVID will establish a hospital at 769 Indiana Avenue, Indianapolis, Indiana, for the exclusive treatment of negroes. The hospital will include a nurses' training school for colored nurses. It will be operated under the name of the Provident Sanitarium Association.

THE Howard County Medical Society held its regular monthly meeting at Kokomo, October 7. Dr. F. S. Cuthbert presented the main paper of the evening, the subject of which was "Diagnosis of some of the more frequently met with complications in the eye, ear, nose and throat practice as it concerns the general practitioner."

THE first fall meeting of the Muncie Academy of Medicine was held at the Hotel Roberts, Muncie, October 23. About 250 physicians were present. The main address of the evening was presented by Dr. I. O. Porter, of Buffalo, N. Y., who is president of the American Gynecological and Obstetrical Society. His subject was "Versions."

THE National Anesthesia Research Society, in convention at Kansas City, October 25, presented a silver loving cup to Dr. Arthur E. Guedel, of Indianapolis, in appreciation of his pioneer work in nitrous oxide obstetric anesthesia. Dr. Guedel has assumed charge of the anesthesia department of St. Vincent's Hospital, Indianapolis.

THE first American Birth Control Conference has been called in New York City for November 11, 12, and 13. There will be discussions on the question of population and social aspect, medical aspect and private discussion of practical methods by authorized delegates, and mass meeting and organization of an American Birth Control League.

MISS ANNETTE B. COWLES of the City Hospital, Indianapolis, was elected president of the Indiana League of Nursing Education at the nineteenth annual convention of the Indiana Nurses' Association. Miss Mary Peterson, of the Robert W. Long Hospital, was made vice-president, and Miss I. L. Goepinger, of the Deaconess Hospital, was made secretary-treasurer.

THE Muncie Academy of Medicine held a meeting at the Hotel Roberts, Muncie, October 28. A paper was given by Dr. Martin H. Fischer, professor of physiology of the University of Cincinnati, on the subject of "Arteriosclerosis". Dr. C. P. Emerson of Indianapolis, Dr. G. W. McCaskey of Fort Wayne, and Dr. Weir Miley of Anderson lead the discussion of Dr. Fischer's paper.

IT was stated at the annual convention of the International Association of Industrial Accident Boards, held in Chicago, September 20, that the economic loss caused by industrial accidents amounted to about $1,000,000,000. The wage loss approximated $853,000,000 and other costs, including surgical, hospital and administrative expense in connection with compensable accidents, added $161,000,000 to the bill.

PREPARATIONS were made for a drive to collect $8,000,000 for the erection of hospitals by the Imperial Council of the Shrine at a meeting of the Hospital Committee held in St. Louis, September 25th. The central hospital, to cost approximately $1,000,000, will be in St. Louis, with others at San Francisco; Shreveport, Louisiana; Portland, Oregon; Minneapolis or St. Paul, Minnesota, and Montreal.

A NUMBER of changes are announced in the faculty of the Yale Medical School. New professors are Dr. Francis G. Blake, Dr. John Slade Ely, professors of medicine, and Dr. Edwards A. Park, professor of pediatrics. Dr. Arthur M. Morse is head of the department of obstetrics and gynecology. New associate professors are Dr. John P. Peters, Jr., department of medicine, and Dr. Alfred T. Shohle, department of pediatrics. Dr. Samuel C. Harvey is in charge of the surgical department of the school, assistant professors being Dr. Clyde L. Deming, urology; Dr. J. J. Morton, Jr., surgery; Dr. Grover F. Powers, pediatrics, and Dr. William C. Stadie, medicine. Dr. Eugene M. Blake has been made assistant clinical professor of ophthalmology.

DURING October the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies:

Davis & Geck:
- Kalmerid Germicidal Tablets, Potassium-Mercuric-Iodide.

Eastman Kodak Company:
- Eastman Barium Sulphate for Roentgenology.

Powers-Weightman-Rosengarten Co.:
- Copper Citrate-P. W. R.
- Mercury Benzoate-P. W. R.
- Mercury Cyanide-P. W. R.
- Mercury Succinimide-P. W. R.
- Silver Citrate-P. W. R.
- Silver Lactate-P. W. R.

Solution Arsphenamine-Lowy: This product has been acquired by E. R. Squibb & Sons, and is retained in New and Nonofficial Remedies as Solution Arsphenamine-Squibb.

A fraternal organization asked a disciple of one of the pseudo-medical cults for a statement concerning an examination of one of their members. The report, given with accuracy but with names omitted, was as follows:

TO WHOM IT MAY CONCERN:

This certifies that Mr. ———— presented himself at my office for physical examination on August 12, 1919.

Upon examination we found the following condition:
A diastolic heart murmur.
Blood pressure low.
Patient losing flesh, is thin and emaciated.
Stomach and bowels full flatus.
Appetite poor.
Constipation.
A moderate hypdaosis of thoracic spine.
Loodosis of cervical and lumbar spine.
Both of above areas of spine markedly stiff and tense.
Patient was advised to rest with treatment, with which he is now complying with improvement.

J. L. W————,
D.O.M.D.D.P.H.

The contributor who favors us with this piece of literature says that the patient is still living and that it is fortunate that such a skillful "doctor", who requires seven letters to enumerate his numerous degrees, had the case in hand.

INDIANA STATE MEDICAL ASSOCIATION

Indianapolis Session, September, 1921

HOUSE OF DELEGATES—FIRST MEETING

The first meeting of the House of Delegates was called to order at seven o'clock, September 28, 1921, by the President, Dr. David Ross of Indianapolis.

Charles N. Combs, the Secretary, called the roll of delegates, and there being a quorum present the House was declared in session.

The President called for the reading of the minutes of the previous session, but on motion of Dr. George R. Daniels, Marion, duly seconded, the minutes as printed in the September number of THE JOURNAL were adopted and the reading at this time dispensed with.

It was moved by Dr. G. D. Miller, Logansport, that the Report of the Secretary-Treasurer as printed in THE JOURNAL be accepted. Motion seconded and carried.

The Secretary mentioned one item of his report—the making of Dr. G. W. H. Kemper an honorary member of this Association, thus making him eligible to be made an Affiliate Fellow of the American Medical Association. It was moved by Dr. William R. Moffit, Lafayette, that Dr. Kemper be made an honorary member of this Association. Motion seconded by Dr. George W. Finley, Brazil, and many others, and unanimously carried by rising vote.

Dr. George F. Keiper, Lafayette, then called attention to another item of the Secretary's report—the long service of some of the county secretaries, especially that of Dr. Allen Pierson, of Spencer, and moved that the congratulations of the Association be extended to Dr. Pierson for his forty years of continuous service in this capacity. Motion seconded and unanimously carried by rising vote.

On motion of Dr. George R. Daniels, Marion, the reports of standing committees as printed were adopted.

The Secretary then read, under the head of "Communications", a letter from Mrs. Marie D. Gorgas, thanking the Association for the resolution of a year ago regarding General Gorgas; also a letter from Dr. G. W. H. Kemper, now in Pasadena, California, to the House of Delegates, which was as follows:

To the House of Delegates of the Indiana State Medical Association:

It is fifty-four years since I attended the Indiana State Medical Association for the first time; this was at the May session of 1867. Since that date I have missed only a few sessions. I learned to cherish these yearly assemblies with a great deal of delight, for they were my true vacation periods—periods of pleasure and profit.

Those were years when the "Transactions" were issued annually and these were in their infancy—merely pamphlets in paper backs. They were not dignified with muslin enclosure until about the year 1874, and this was the fashion until they ceased to exist in 1907, giving way to our splendid Journal in 1908. These pamphlets and volumes—58 in number (1847-1907)—contained 1202 articles contributed by 481 physicians and scientific men. Many of these essays may be read with advantage at the present day when we have made so much advancement in medical science.

When I attended the session of the State Medical Association of 1867, I met with a number of remarkable men. They were no ordinary physicians for that period. All have gone upon that unreturning visit. Here again I met Dr. John S. Bobbs. I first saw him on the 24th day of May, 1861, when I was a private soldier in Co. B of the 7th Regiment, Indiana Volunteer Infantry—three months' service. On the day named five of the Indiana regiments were reviewed at Indianapolis, by General George B. McClellan. On this occasion Dr. Bobbs rode with the three Governors: Morton of Indiana, Dennison of Ohio, and Yates of Illinois. These men, and I presume nearly all the men into whose faces they looked at that parade, have fallen asleep. I believe I am the "last leaf" of the early members of the Indiana State Medical Association. I am not aware of others. Possibly I am the ranking living member. The Association always has treated me liberally. For a number of years I was treasurer. I am the senior living ex-president of the society, having been elected president in 1886, and presided the following year—1887—thirty-four years ago last May. I was elected the first delegate to the American Medical Association in 1902. I held the position of councilor from 1903 to 1920. I served twenty years as chairman of the committee on necrology. I am sure that my medical brethren will pardon these personal references in this letter. I simply dropped into a historical reverie for the moment.

It would afford me much pleasure to meet with the Association which will convene this present month, but I am far away. Possibly it is better that I remain for a longer period in this milder climate. California, with its beautiful hills, valleys and mountains decorated with lovely flowers, is unsurpassed by no other country that I have visited. And yet, I love more dearly my own native state of Indiana. In that fine poem—"The Deserted Village"—Goldsmith makes his poet wish that after his long and wild wanderings were over that he might find a burial spot in his early home.

"And as the hare whom hounds and horns pursue,
Pants to the place from which at first she flew;
So had I hoped, life's long vexation past,
Here to return and die at home at last."

My health has gradually improved—thanks to my good friend, Dr. W. N. Wishard, and a Kind Providence.

With love for the Association and all its members,
G. W. H. KEMPER.

Pasadena, Calif., Sept. 20, 1921.
1239 E. Orange Grove Ave.

It was taken by consent that the letter of Mrs. Gorgas be filed as a matter of record, and that the Secretary be instructed to reply to Dr. Kemper's letter.

Dr. William R. Phillips, of Connersville, then spoke on the subject of medical legislation, especially that affecting the Medical Practice Act. This discussion was continued by Drs. J. A. Craig, Greenwood; Edward E. Evans, Gary; Charles H. McCully, Logansport; Elmer E. Morgan, Fort Wayne, and G. G. Eckhart, Marion.

It was then moved by Dr. Wm. R. Phillips that a committee of five be appointed by the Chair to draw up resolutions covering this matter, this committee to report to the House of Delegates Friday morning. Motion seconded by Dr. Franklin S. Crockett, Lafayette, and carried.

The president appointed the following committee: William R. Phillips, Connersville; George R. Daniels, Marion; J. A. Craig, Greenwood; Franklin S. Crockett, Lafayette; Edward E. Evans, Gary.

Dr. George F. Keiper then called attention to the Indiana State Hospital Association, recently organized, and moved that this Association send its greetings and best wishes to the Hospital Association. Motion seconded and carried.

No further business appearing, the House of Delegates adjourned until Friday morning at eleven.

CHAS. N. COMBS, Secretary.

HOUSE OF DELEGATES—SECOND MEETING

The second meeting of the House of Delegates was called to order by President Dr. David Ross at 11:00 a. m., Friday, September 30th.

Election of officers for the year 1922 was the first order of business, and resulted as follows:

President—Dr. W. R. Davidson, Evansville.

First Vice-Pres.—Dr. Thomas M. Jones, Anderson.

Second Vice-Pres.—Dr. John H. Reed, Logansport.

Third Vice-Pres.—Dr. E. S. Jones, Hammond.

Sec'y-Treas.—Dr. Charles N. Combs, Terre Haute (re-elected).

Delegates to the American Medical Association for the ensuing two years: Dr. Albert E. Bulson, Jr., Fort Wayne; Dr. George F. Keiper, Lafayette.

Alternates: Dr. E. H. Griswold, Peru; Dr. Harry Elliott, Brazil.

Dr. E. M. Shanklin, of Hammond, was re-elected chairman of the Committee on Administration and Medical Defense for the ensuing three years.

Dr. W. H. Stemm, of North Vernon, was re-elected on the Committee on Hospital Standardization for the ensuing five years.

The following councilors were elected, their terms to expire December 31, 1924: Second District, Joseph Schmadel, Vincennes; Fifth District, Joseph H. Weinstein, Terre Haute.

The eighth and eleventh councilor districts reported that their councilor would be elected before the end of the year.

Dr. W. R. Phillips, Connersville, submitted the report of his committee Wednesday night, and, as amended, was adopted as follows:

WHEREAS, The past decade has demonstrated the extreme difficulty of securing the passage of good medical legislation or of measures designed to strengthen the present laws, and

WHEREAS, There is an increasing tendency on the part of certain cults and classes to ignore laws as they now exist, and

WHEREAS, Such conditions tend to undermine the laws of the state and to weaken and eventually destroy the medical fabric as it now exists, thereby producing an irreparable loss to all concerned; therefore be it

RESOLVED, That it is the sense of this Association that we should, within the body of the profession itself, seek to build up a method of defense of the rights of the profession and of the safety of the public at large. Be it further

RESOLVED, That we urge that greater power be given the Committee on Public Policy and Legislation, and that a standing vote of thanks and appreciation be accorded the venerable and honorable chairman of the Committee, Dr. Wm. N. Wishard, for his untiring and ceaseless efforts to upbuild and uphold the legal fabric of the profession of Indiana. Be it further

RESOLVED, That we seek to promulgate a stronger organization to bring about a closer and more complete and efficient co-operation among the several county societies; and be it further

RESOLVED, That any of the funds of the Association not in excess of $5,000 be, and the same is hereby rendered available, under the direction of the Council, for the investigation and prosecution of violation of the present medical laws.

Dr. Lafayette Page, of Indianapolis, spoke on the needs of the proposed Riley Memorial Hospital, and appealed for its support.

Dr. Albert E. Bulson, Jr., moved that the Indiana State Medical Association endorse the project of establishing the Riley Memorial Hospital for *indigent* children of the State.

Moved, seconded and carried.

Dr. J. R. Newcomb, Indianapolis, moved that we heartily endorse the invitation of the Eye, Ear, Nose and Throat Section of this Association to the Academy of Ophthalmology and Otolaryngology to hold its 1922 session in Indianapolis.

Consent.

Dr. A. E. Sterne, Indianapolis, chairman of the Committee on Hospital Standardization, introduced the following resolution as a supplementary report, and, after considerable discussion, it was adopted as follows:

Realizing that the Hospital Standardization Classification in Indiana and other states of the United States is admittedly confused and chaotic, chiefly for the reason that different agencies are attempting to classify hospitals and institutions without concerted, considerate effort, and, realizing further, that a continuance of such a policy will maintain and augment the chaos and difficulties of the entire hospital question, and believing that the A. M. A. through its Council on Education and Hospitals should assume and retain the leadership in this matter, and affirming its confidence in the ability and integrity of this leadership, the House of Delegates of the Indiana State Medical Association petitions the Council on Education and Hospitals of the A. M. A. and respectfully suggests:

First, That the Council invite the proper committees of various recognized medical organizations, actively engaged in hospital standardization work, to meet in joint conference, in order to unify and coordinate the efforts of the several organizations to attain a standard classification of the hospitals of the United States; and

Second, Further suggests that the Council on Medical Education and Hospitals, at an early date and appointed place, call a meeting of the chairmen and other members of the Hospital Standardization Committees of the component state medical associations, and any other properly accredited delegates from these associations, in order that this work may be conducted in the various states upon similar lines and upon unified standards.

Dr. J. M. McCoy, of Vincennes, proposed that the Association investigate the plan of adopting group automobile liability insurance for the members. The incoming president was instructed to appoint a committee of five to investigate this question.

Dr. George R. Daniels, Marion, moved a vote of thanks to the Indianapolis Medical Society for the splendid entertainment provided for this annual session.

Carried.

By unanimous vote, the next annual session is to be held at Muncie, September 27th, 28th and 29th, 1922.

Adjournment. CHAS. N. COMBS, Secretary.

THE COUNCIL—FIRST MEETING

The first meeting of the Council was held at the Claypool Hotel, Indianapolis, Wednesday, September 28th, at 4:30 p. m. Called to order by the Chairman, Dr. E. M. Shanklin.

Present: Drs. S. E. Earp, W. R. Moffit, E. M. Shanklin, J. B. Berteling, G. G. Eckhart, C. N. Combs and President Dr. David Ross.

The minutes of the previous meetings were read and accepted.

The councilors made reports of their respective districts, and discussion ensued concerning the status of the profession in Starke County. An effort will be made before the end of this year to rehabilitate the Starke County Medical Society, or if that is not possible, the county will be joined to that of Pulaski.

A letter was read from Dr. W. N. Wishard, urging the annual publication of the list of members of the Indiana State Medical Association to be available for officers and committeemen. The secretary was instructed to ask the editor to publish this list in the December number of THE JOURNAL.

Adjourned. CHAS. N. COMBS, Secretary.

THE COUNCIL—SECOND MEETING

The last meeting of the Council was held Friday, September 30th, at 1:30 p. m.

Present: Drs. S. E. Earp, W. R. Moffit, W. J. Leach, F. J. Spilman, J. H. Willis, A. E. Bulson, Jr., and C. N. Combs.

After discussing the funds to be made available for the new Committee on Public Policy and Legislation, it was moved and carried that the Council ask the new Committee to attend the mid-winter meeting of the Council in January.

It was suggested that the annual session would be more notable if out-of-state guests were invited by each section, and the Council recommends to the section officers to invite a guest for each section for the coming session.

Adjournment. CHAS. N. COMBS, Secretary.

MINUTES OF GENERAL MEETING

Indianapolis Session, September, 1921

The first general meeting of the Indiana State Medical Association was called to order at nine a. m., September 29, 1921, in the Assembly Room of the Claypool Hotel, Indianapolis, by the President, Dr. David Ross, of Indianapolis.

The Mayor of Indianapolis was not present, but Dr. Ross in a few words welcomed the members of the Association.

Dr. Miles F. Porter, of Fort Wayne, was given the privilege of the floor for a few minutes to present the claims of the American Society for the Control of Cancer. Dr. Porter is the Chairman of the Indiana branch of this Society.

The President, Dr. David Ross, of Indianapolis, read his address, entitled "Medicine and State Control". (Published in this number of THE JOURNAL.)

Dr. B. W. Rhamy, of Fort Wayne, read a paper entitled "Ulcer of the Stomach and Duodenum: Etiology and Pathology."

Dr. W. H. Foreman, Indianapolis, read a paper on "Ulcer of the Stomach and Duodenum: Diagnosis and Medical Treatment."

Dr. J. R. Eastman, Indianapolis, read a paper entitled "Ulcer of the Stomach and Duodenum: Surgical Technique."

The above symposium was discussed by Drs. Miles F. Porter, Fort Wayne; A. B. Graham, Indianapolis; W. D. Asbury, Terre Haute; Frank W. Foxworthy, Indianapolis; G. W. McCaskey, Fort Wayne; H. O. Pantzer, Indianapolis, and in closing by Drs. W. H. Foreman and J. R. Eastman.

Dr. Charles P. Emerson, Indianapolis, read a paper entitled "Treatment of Chronic Nephritis". This paper was discussed by Drs. G. W. McCaskey, Fort Wayne, and E. F. Kiser, Indianapolis.

The General Meeting adjourned until Friday afternoon at two o'clock.

Second Meeting

The second General Meeting of the Indiana State Medical Association was called to order at 2:20 p. m., September 30, 1921, by the First Vice-President, Dr. Hugh J. White of Hammond.

Dr. H. R. Allen, Indianapolis, read a paper entitled "The Treatment of Club Feet". This paper was discussed by Drs. G. D. Marshall, Kokomo; Oscar T. Scamahorn, Pittsboro, and by Dr. H. R. Allen in closing.

Dr. G. B. Jackson, Indianapolis, presented a paper on "Sterility in the Female". This paper was discussed by Dr. O. G. Pfaff, Indianapolis, and Dr. Arnold Province, Franklin.

The chairman then announced that Dr. W. R. Davidson, of Evansville, had been elected President of the Association for the ensuing year, and that the place of meeting for 1922 would be Muncie.

Dr. E. B. Mumford, Indianapolis, read a paper entitled "The Treatment of Compound Fractures". This paper was discussed by Drs. H. O. Bruggeman, Fort Wayne; H. R. Allen, Indianapolis, and the discussion closed by Dr. E. B. Mumford.

Dr. W. U. Kennedy, Newcastle, read a paper entitled "Traumatic Abdominal Injuries". This paper was discussed by Dr. W. P. Williams, Lebanon, and the discussion closed by Dr. W. U. Kennedy.

The program being finished, the General Meeting adjourned.

MINUTES OF SECTION ON SURGERY

Indianapolis Session, September, 1921

The first meeting of the Section on Surgery was called to order at 2:10 p. m., September 29, 1921, in the Assembly Room of the Claypool Hotel, Indianapolis, by the Chairman, Dr. Charles C. Terry, of South Bend.

Dr. W. H. Baker, South Bend (together with Dr. M. W. Lyon, Jr.), presented a paper on "Cecal Tuberculosis". This paper was discussed by Drs. J. H. Eberwein, Indianapolis; A. S. Jaeger, Indianapolis; John Sluss, Indianapolis; B. Van Sweringen, Fort Wayne; Goethe Link, Indianapolis; W. H. Williams, Lebanon, and in closing by Dr. W. H. Baker.

Dr. H. K. Bonn, Indianapolis, read a paper entitled "Operative Injury of the Hepatic and Common Bile Ducts. Methods of Avoidance and Repair." This paper was discussed by Drs. H. O. Shafer, Rochester; Goethe Link, Indianapolis; B. Van Sweringen, Fort Wayne; Ernest I. Brenner, Winchester; A. S. Jaeger, Indianapolis, and in closing by Dr. H. K. Bonn.

Dr. Murray N. Hadley, Indianapolis, read a paper entitled "Local Anesthesia as a Supplement to General Narcosis". This paper was discussed by Drs. A. C. Arnett, Lafayette; Frank H. Jett, Terre Haute, and the discussion closed by Dr. M. N. Hadley.

Dr. James Y. Welborn, Evansville, read a paper entitled "Conclusions from My Experience in Appendicitis". This paper was discussed by Dr. G. D. Scott, Sullivan, and in closing by Dr. James Y. Welborn.

Dr. A. S. Jaeger, Indianapolis, read a paper entitled "Notes on the Treatment of Septic Infection Following Delivery or Abortion". This paper was discussed by Drs. Joseph H. Weinstein, Terre Haute; Frank S. Holland, Bloomington, and the discussion closed by Dr. A. S. Jaeger.

The Section adjourned until nine o'clock Friday morning.

Second Meeting

The second meeting of the Section on Surgery was called to order at 9:25 a. m., September 30, 1921, by the Vice Chairman, Dr. H. K. Bonn, of Indianapolis.

The paper of Dr. P. E. McCown, Indianapolis, on "Non-Tuberculous Infection of the Kidney" was read by Dr. Frank G. McCarthy, of Terre Haute, Dr. McCown being absent on account of illness. This paper was discussed by Drs. Charles Barnett, Fort Wayne; Bernard Erdman, Indianapolis; H. O. Mertz, Indianapolis, and J. F. Cameron, Fort Wayne.

Drs. J. H. Oliver and V. H. Moon read papers on "Osteitis Fibrosa and Osteitis Fibrosa Cystica". These papers were discussed by Drs. Charles M. Mix, Muncie; G. D. Marshall, Kokomo.

The election of officers for this Section took place at this time, resulting as follows: Chairman, A. S. Jaeger, Indianapolis; Vice Chairman, T. C. Kennedy, Indianapolis; Secretary, H. W. McDonald, Newcastle.

Dr. Stanley A. Clark, South Bend, read a paper on "The Treatment of Cancer of the Uterine Cervix". This paper was discussed by Drs. Grace Line Homan, Laporte; George Kohlstadt, Indianapolis; Albert M. Cole, Indianapolis; Thomas C. Kennedy, Indianapolis; O. E. Spurgeon, Muncie; H. O. Shafer, Rochester, and in closing by Dr. Stanley A. Clark.

Dr. W. D. Gatch, Indianapolis, read a paper entitled "The Clinical History of Tumors of the Face and Jaws as a Guide to Their Correct Diagnosis and Proper Treatment". This paper was discussed by Drs. T. C. Kennedy, Indianapolis; Albert M. Cole, Indianapolis; Edwin N. Kime, Indianapolis; W. U. Kennedy, Newcastle; H. K. Bonn, Indianapolis, and in closing by Dr. W. D. Gatch.

The Section adjourned.

MINUTES OF THE SECTION ON MEDICINE
Indianapolis Session, September, 1921

The first meeting of the Section on Medicine of the Indiana State Medical Association was called to order in the Claypool Hotel, Indianapolis, at 2:15 p. m., by the Vice-Chairman, Dr. George G. Richardson, Van Buren.

Dr. Maurice H. Krebs, Huntington, presented a paper on "Foreign Bodies Within the Respiratory Tract as Causative Factors in the Production of Pathological Conditions".

This paper was discussed by Drs. Alfred Henry, Indianapolis; C. A. Sellers, Hartford City; John Barnhill, Indianapolis; and George G. McConnell, Indianapolis, and the discussion was closed by Dr. Krebs.

Dr. W. A. Fankboner, Marion, read a paper on "Epidemic Encephalitis".

This paper was discussed by Drs. E. O. Daniels, Marion; Clay Ball, Muncie; George F. Beasley, Lafayette; Chas. F. Neu, Indianapolis; Chas. D. Humes, Indianapolis; P. B. Carter, and Albert E. Sterne, Indianapolis, and in closing by the essayist.

Dr. Jane Ketcham, Indianapolis, presented a paper on "Eclampsia".

This paper was discussed by Drs. Fred R. Clapp, South Bend; Chas. S. Bond, Richmond; Elmer E. Morgan, Fort Wayne; Wm. F. Smith, Huntington; Chas. H. Good, Huntington; Morris H. C. Johnson, Vincennes, and the discussion was closed by the essayist.

Dr. Charles G. Beall, Fort Wayne, read a paper entitled "Functional Nervous Disturbances in Soldiers and Civilians".

This paper was discussed by Drs. W. D. Asbury, Terre Haute; Chas. D. Humes, Indianapolis, and the discussion was closed by Dr. Beall.

The Chairman explained that Dr. James L. Gilbert, of Logansport, was unable to be present on account of illness, and moved that the Secretary be instructed to send a message of sympathy from the Section to Dr. Gilbert, and that his paper be released so that it might be read and published by Dr. Gilbert wherever he saw fit.

Supported by several members and unanimously carried.

Adjournment at 5:45 p. m. to reconvene at 9:00 a. m. Friday, September 30.

Second Meeting

The second meeting of the Section on Medicine was called to order at 9:00 a. m. by the Chairman, Dr. Fred R. Clapp, South Bend.

Election of Officers:

The following gentlemen were elected as Section Officers for the ensuing year: Chairman, Dr. Geo. G. Richardson, Van Buren; Vice-Chairman, Dr. Roscoe H. Beeson, Muncie; Secretary, Dr. Byrl R. Kirklin, Muncie.

Dr. Arlie R. Barnes, Rochester, Minnesota, presented a paper entitled "Bacteria Recovered Post-Mortem. With Special Reference to Selective Localization and Foci of Infection".

This contribution was discussed by Drs. Virgil Moon, Indianapolis; George W. McCaskey, Fort Wayne; Henry R. Alburger, Indianapolis; Frank Wynn, Indianapolis, and Robert V. Hoffman, South Bend, and in closing by the essayist.

Dr. R. V. Hoffman, South Bend, read a paper on "Some Problems in Syphilis".

This paper was discussed by Drs. Wm. S. Ehrich, Evansville; George W. McCaskey, Fort Wayne; A. W. Brayton, Indianapolis; W. A. Fankboner, Marion, and the discussion was closed by Dr. Hoffman.

Dr. John W. Sluss, Indianapolis, presented a paper on "Infections of the Gall Bladder".

This paper was discussed by Drs. W. D. Asbury, Terre Haute; Wm. H. Foreman, Indianapolis; Geo. W. McCaskey, Fort Wayne; George W. Spohn, Elkhart, and the discussion was closed by Dr. Sluss.

Dr. George W. Spohn, Elkhart, read a paper entitled "The Physical Inequality of School Children".

This paper was discussed by Drs. Ada E. Schweitzer, Indianapolis; George V. Cring, Portland; A. W. Brayton, Indianapolis, and the discussion was closed by Dr. Spohn.

Dr. Charles S. Woods, Indianapolis, presented a paper on "Professional Efficiency in the Hospital".

This contribution was discussed by Drs. H. G. Hamer, Indianapolis; A. C. Kimberlin, Indianapolis; Charles E. Barnett, Fort Wayne.

As this completed the program, on motion duly seconded and carried, the Section on Medicine adjourned at 12:40 *sine die*.

SECTION ON OPHTHALMOLOGY AND OTOLARYNGOLOGY
Indianapolis Session, September, 1921

The Section on Ophthalmology and Otolaryngology of the Indiana State Medical Association met in Parlor B of the Claypool Hotel, Indianapolis, Indiana, at two o'clock p. m., on Thursday, September 29, 1921, with the Chairman of the Section, Dr. W. A. Hollis, of Hartford City, presiding.

Dr. Keiper exhibited to the Section a microscopic specimen showing a patch of choroidal atrophy.

Dr. Hollis called Dr. McCasky to the Chair, and read a paper entitled "Some Professional Shortcomings".

This paper was discussed by Drs. Shanklin, Stucky (of Lexington, Kentucky), Breitenbach, and Adams, and in closing, by Dr. Hollis.

Dr. Hollis resumed the Chair.

Dr. Howard, of Warsaw, read a paper entitled "Report of a Case of Bezold's Mastoiditis, Preceded by Thirty Years of Middle Ear Suppuration".

This paper was discussed by Drs. Lent, Boyd-Snee, Edgar, Sautter and Barnhill, and the discussion was closed by Dr. Howard.

Dr. J. A. Stucky, of Lexington, Kentucky, read a paper entitled "Trachoma or Folliculosis Among School Children".

This paper was discussed by Drs. Shanklin, Larkin, Bulson, Keiper, Newcomb, Rariden and Kearby, and the discussion was closed by Dr. Stucky.

There being no further business to come before the Section, on motion duly made, seconded and carried, the Section adjourned until Friday, September 30, 1921, at nine o'clock a. m.

Second Meeting

The second meeting of the Section on Ophthalmology and Otolaryngology was called to order at 9:00 a. m., Friday, September 30th, by the Chairman, Dr. William A. Hollis.

The election of officers for the ensuing year resulted as follows: Chairman, Dr. C. H. McCasky, Indianapolis; Vice-Chairman, Dr. Chas. J. Adams, Kokomo; Secretary, Dr. E. M. Shanklin, Hammond.

Dr. Keiper moved that the Section invite the American Academy of Ophthalmology and Otolaryngology to meet in Indianapolis next year, and that this invitation be extended at the session of the Academy, at Philadelphia, on the 17th of October next. Motion carried.

Dr. Shanklin moved that the Section extend to Dr. J. A. Stucky its thanks for coming here and giving to the Section his estimable paper.

The motion was seconded, and prevailed.

Dr. Kearby read a paper entitled "What the General Practitioner Can Do in Otology".

This paper was discussed by Drs. Spohn, Bulson, Keiper, McCasky, Krebs and Hollis, and the discussion was closed by Dr. Kearby.

Dr. George F. Keiper read a paper entitled "Sand Bur in the Larynx, Report of a Case. Endoscopic Removal."

This paper was discussed by Drs. Layman, Bulson and Knapp, and the discussion was closed by Dr. Keiper.

Dr. Harry Boyd-Snee, of South Bend, read a paper entitled "The Clinical Picture of Streptococcic Osteomyelitis of the Temporal Bone".

This paper was discussed by Drs. Breitenbach, Cuthbert, Bulson, Tomlin and Howard, and the discussion was closed by Dr. Boyd-Snee.

Dr. William F. Molt, of Indianapolis, read a paper entitled "Ludwig's Angina, Complicating Acute Suppuration of the Parotid Gland".

This paper was discussed by Drs. Boyd-Snee and Berry.

There being no further business to come before the Section, on motion duly made, seconded and carried, the Section adjourned, *sine die*.

MONTGOMERY COUNTY

At a special meeting of the Montgomery County Medical Society, held at the Masonic Temple, October 25, a committee consisting of Drs. W. T. Gott, F. A. Dennis and J. R. Etter was appointed to prepare a suitable memorial on the demise of Dr. Samuel L. Ensminger, which occurred September 25, 1921.

Preamble:

Samuel L. Ensminger graduated from the Miami Medical College in 1874 and soon thereafter began the practice of medicine in Crawfordsville, being for a number of years associated with Drs. McClelland and Cowan. He continued to practice in Crawfordsville during the remainder of his active life. He served in the Union army during the Civil War, being severely wounded. He was a member of the Montgomery County Medical Society, having served it as secretary and president, and was a member of the Indiana State Medical Association and the American Medical Association. He had the confidence and respect of the community in which he practiced for more than forty-seven years.

RESOLVED, By the Montgomery County Medical Society, That in the death of Dr. Samuel L. Ensminger, this Society has lost a valued member, who was always willing to do his duty. Be it further

RESOLVED, That this memorial be spread on the records of the Society, and a copy presented to the family, who have our deepest sympathy.

Special meeting of the Montgomery County Medical Society, October 25, 1921.

On account of the death of Dr. William F. Batman, President of the Society, the vice-president called a special meeting to attend the funeral and take suitable action in the matter. A committee, consisting of Drs. W. T. Gott, E. A. Dennis and J. R. Etter, was appointed to draft a suitable memorial in his behalf.

Preamble:

William F. Batman was graduated from the Jefferson Medical College in 1880, and practiced medicine at Roachdale, Ladoga and Crawfordsville. He joined the Montgomery County Medical Society, March 20, 1900. At the time of his death he was president of the Society. He was a member of the Indiana State Medical Association and the American Medical Association. He was an honored member of the medical profession, and a worthy citizen. His demise occurred October 23, 1921.

RESOLVED, By the Montgomery County Medical Society, That in the death of Dr. Batman we have lost a valuable co-worker, and that a copy of these resolutions be placed on the records of the Society, a copy be presented to the family, who have our deepest sympathy.

MUNCIE ACADEMY OF MEDICINE

September 23, 1921

The Muncie Academy of Medicine met at the Hotel Roberts at 6:15 p. m. on Friday evening, September 23rd, for the regular dinner meeting. The business routine was waived and Dr. Irving Potter, of Buffalo, the guest of the Academy and the speaker of the evening, was introduced by President B. R. Kirklin. Dr. Potter's subject was "Version" and the address was illustrated by lantern slides.

Synopsis:—In 1130 cases of version the mortality has been 2.3 percent. The mortality in version is no higher than in any other method of delivery. There should be no morbidity in versions. In version the woman has the first stage of labor only; there is no second stage to the delivery. Following delivery by version the patient is put on her stomach in the second 24 hours. On the 8th day she is placed in the knee-chest position for ten minutes. On the 10th day she gets up and on the 13th day goes home. Sometimes patients go home on the 12th day. There is less lochia and no ballooning of the uterus. Some people have said that the mother cannot nurse the baby because there is no second stage of delivery. I wish to say that version has no effect on the milk.

The baby is weighed at birth and every day until it leaves the hospital. We find that they get the birth weight back quicker than other babies and they leave the hospital on the 13th day with a considerable increase of the birth weight. As to injury to the child, in doing 4000 versions I have broken one arm in a live baby. This case was one of a big baby and a small pelvis. I have twice broken the arms of dead babies in the interest of the mother and when I knew the baby was dead. There are fewer lacerations with properly performed version than any other method. I do no episiotomies. At the present time I do not believe that labor should be induced. No cystocele and no rectocele follows version.

DISCUSSION

DR. O. G. PFAFF, Indianapolis, Indiana—From the standpoint of most of us, version is a revolutionary proceeding just as ovariotomy was in McDowell's time. One New York man has said that he did not believe version could be taught in medical colleges; that it was Dr. Potter's own skill and ingenuity that made it a success in his hands and that we could not teach anybody else to do it. In answer to this Dr. Potter said, "I will guarantee to teach anybody to do these things as well as I do." Not all medical students are skilled in major surgery and not all are skilled in obstetrics. Obstetrics is beginning to be a real specialty. The man who desires to become a specialist in obstetrics must equip himself to become a specialist. I would like to ask Dr. Potter if he can prove that there is no traumatism by ironing out the birth canal. If so I can see no objection to adopting Dr. Potter's version by the obstetrical specialist.

DR. A. M. MENDENHALL, Indianapolis, Indiana—I believe that version should be discussed from the standpoint of technique and indication. We have been taught in the past certain indications for version, among them face presentation, prolapsed cord, transverse presentation, occiput posterior presentation, eclampsia, etc. Such unusual indications are serious conditions. Dr. Potter has proven the right to a separate consideration of version. In most instances it has been done as a last resort. The indication back of version is the real consideration. Personally I feel that version should be a substitute for high forceps. High forceps is the most unsurgical of all surgical procedures. Dr. Potter anticipates trouble by going ahead with version. His method is distinct. The scapula should be well out before delivery of the arm. Dr. Potter goes contrary to all textbooks in regard to speed. His time is longer. The baby does not die in 8 minutes. The second stage is painless; there is no laceration, less necrosis, less shock to the mother and less injury to the baby. It has been shown at autopsy that 50 percent of still born babies die of head injury in spontaneous delivery. There are no third degree lacerations in delivery by version. It might be of interest to you to know that the fetal mortality for the year ending the first week of March, 1920, in Indianapolis was 3.6 percent; in Indiana, 3.8 percent; in Muncie, 6 percent; Dr. Potter, 2.3 percent.

DR. CHARLES MARVEL, Richmond, Indiana—For the last two or three years I have applied version to all malpositions in my work. In my mind it is a question as to whether all men should do version or not. I believe that version is for the man who is sure of his technique. Are all cases of obstetrics version? I believe that if version is done properly it is as safe as a normal delivery.

DR. M. C. SEXTON, Rushville, Indiana—Some time ago I had the pleasure of being in Buffalo and seeing Dr. Potter do some work. There were four cases, the first a woman of 28 years, second baby; the os was completely dilated; Dr. Potter after making the preliminary steps of his version said that the case could not be delivered by version as the os could not be dilated sufficiently; vigorous six and one-half pound baby was delivered by high forceps. Second case, primapara, age 37, delivery in 14 minutes. Third case was breach presentation; worked on baby after delivery about 30 minutes with intra-tracheal tube. Fourth case was right occipito posterior. Baby born dead before Dr. Potter reached the patient.

DR. H. F. BECKMAN, Indianapolis, Indiana—I am sure we are all impressed with Dr. Potter's analysis of his method and that we are all under great obligations for his coming before us and giving us what he has. Unfortunately the human mind is more intent upon taking up and grasping the dramatic than on grasping detail and painstaking small points. They are impressed with version but not so much impressed with what occurs before and following version. I would not advise version indiscriminately. The rigid asepsis and painstaking care under which version is done are points which should impress us rather than the point of version itself. This care and preparation which Dr. Potter has are not the result of version but of acumen and of keenness in detail.

DR. JANE KETCHAM, Indianapolis, Indiana—Some time ago I had a chance to try Dr. Potter's method. Patient was a negress weighing 250 pounds. She had been in labor a long time; this was the 16th pregnancy; she had a complete ventral hernia. Version such as Dr. Potter described was done. I think that version is a very good method of delivering a breach; it is easier than other methods. Surgical asepsis is very important. If there is not time to wait for complete dilatation of the cervix there will be trouble.

DR. C. J. ROTHSCHILD, Fort Wayne, Indiana—I would like to ask what Dr. Potter's method is in delivering twins.

DR. H. D. FAIR, Muncie, Indiana—Would like to ask if Dr. Potter makes a vaginal examination.

DR. H. A. DUEMLING, Fort Wayne, Indiana—I think it is well to consider the surgical aspect of obstetrics. It is of interest to surgeons to know what is going on in obstetrical work. Dr. Potter practices absolute cleanliness. Cleanliness plays an important role in mortality in obstetrics and in all other conditions we are called upon to treat.

DR. E. F. KISER, Indianapolis, Indiana—Shall we teach Dr. Potter's method in the medical schools? I cannot believe that this method has a place in the medical school.

DR. A. L. KANE, Fort Wayne, Indiana—Version has been taught in complicated cases as a matter of necessity. If all medical schools could be taught this it would be a valuable addition to the curriculum. Since version is a method of doing obstetrics I believe that this method should be taught in the medical schools.

DR. MILES F. PORTER, Fort Wayne, Indiana—I think it is only fair to call your attention once more to caution. Do not be stampeded by statistics. I still believe that chloroform is not the best anesthetic in obstetrics or any other branch of surgery. I cannot altogether accept that version is the ideal method for obstetrics in general practice. With all due respect to Dr. Potter, I must confess I am still "from Missouri" and considerable of a "doubting Thomas".

DR. L. P. DRAYER, Fort Wayne, Indiana—I wish to support Dr. Miles F. Porter's objection to chloroform. I do not advocate the use of chloroform in obstetrics or any other surgical procedure.

DR. WOOLERY, Bloomington, Indiana—I believe Dr. Potter has made a success of version because he has developed it to an art; it is his hobby. He does it with quietness, ease and skill because it has become an art with him.

DR. POTTER'S closing discussion:—I agree with Dr. Mendenhall that high forceps are things of the past. No one here can say how much trouble he has gotten away from by doing elective version. The method is increasing in popularity with the women. They consider favorably the elimination of the second stage and I think that after all it is the women that have the babies and a woman should have her choice of obstetrics. When I hear of a second stage lasting 24, 36, or 38 hours, it makes me sick. I can demonstrate this thing. I have given some men some ideas that they have carried away and developed. Any man with anything above the ears, any judgment

or obstetric training can school himself to do this work. I hope the time will never come when I cannot choose my method of delivering women. I must judge with the individual against the use of forceps. Another thing, a breach case is not a version. You cannot flex the head in a breach case. In version you have flexion and maintain it. If you lose it you are lost. The preparation is a very important thing. Preparation for anything is important. We do not have any post-partum infections. The temperature very rarely goes above 99.5 or 100 on our charts. I never want to see consultation cases. You are called in when an arm is hanging out and you are expected to carry the load of responsibility. Some people think you cannot do version in a primipara. It is as easy to do version in a primipara as in the majority of other cases. In delivering twins I try to lift the lower one up and get the anterior one. I am always very careful not to lock twins. This means death. I have delivered women by version without opening up the old scar. I make all vaginal examinations. I give no antepartum enemas. I do not care what you think about chloroform. Everyone is entitled to his own opinion as to anesthetics. I have one man who gives all my anesthetics. If you cannot have an anesthetist bring someone with you who can give the anesthetic. No man has any business to be an anesthetist, obstetrician and night watchman at one time. My anesthetist has given 3500 chloroform anesthetics with no trouble. I like chloroform because it is pleasant to take, quick in action and gives the most profound relaxation; the patient returns to consciousness very quickly. The general practitioner can do version.

Attendance 287.

Adjournment.

October 24, 1921

The weekly dinner meeting of the Muncie Academy was held at the Roberts Hotel at 6:15 p. m. October 24, 1921. The meeting was called to order by President Dr. B. R. Kirklin.

Dr. I. N. Trent announced the program of activity for the coming Cancer Prevention Week. All doctors of the Academy have signified their willingness to help carry out the program and a doctor has been appointed to speak at each church in the city on Sunday morning on the subject of Cancer Prevention.

Dr. Hollis, of Hartford City, outlined the plans for the program for Cancer Prevention Week to be carried out in Hartford City.

Dr. Moore, as chairman of the Program Committee, gave the program for future meetings as follows: November 4th, joint meeting of the Muncie Academy of Medicine and Delaware-Blackford Medical Society with program on the subject of Control of Cancer; November 11th, program by internes of the Long Hospital, Indianapolis; November 18th, Dr. A. C. Kimberlin, of Indianapolis, "The Psychic Control of Cardio Vascular Patients."

The address of the evening was given by Dr. Martin Fischer, of Cincinnati, his subject being "Arterio-Sclerosis".

Synopsis:—In considering the subject of arterio-sclerosis, we should go over the evidence of the last thirty or forty years and see if there is not a better and more hopeful way of treating arterio-sclerosis. Arterio-sclerosis is a name which I wish to simplify by the term "vascular disease". Arterio-sclerosis means a thickening of the arteries. Two things greatly determine the diagnosis of arterio-sclerosis. One is the anatomic thickening of the arteries and veins. The other thing is increased blood pressure. To the two signs and symptoms which are characteristic of vascular disease another may be added, but it is not a part of the disease but a consequence. This symptom is cardiac hypertrophy. One cause for the lessening of elasticity of the vessels may be due to spasm. The less elasticity the narrower the artery. As a consequence there is an increased amount of work for the heart and the extra work results in hypertrophy of the heart. But hypertrophy of the heart in itself is not a bad thing. I believe that prominent among the causes of vascular disease are hard work and worry. Alcoholism used to be another cause. Some of these things are bad, but I do not think any one of them ever gave vascular disease to anybody. The lesions of vascular disease are always spotty, even in the advanced stage. High blood pressure and vascular disease are due to infection. It has been found that when rabbits are fed a diet of adrenal gland and spleen they develop a high blood pressure which can be maintained for months and months. These animals do not develop vascular lesions. Hypertrophy of the heart as a cause of vascular disease is plain bunk. It is only a sign and a consequence of vascular disease in the blood vessels. The treatment depends on which branch is affected and on the origin in which the lesions occur. Vascular disease is not a disease of the large but of the small blood vessels or capillaries. Depending on where we get these lesions we have anemia of that part, and if there is no possibility of re-establishing the blood supply of the part, the part dies. The most significant lesions are those of the brain and kidney. The insane are for the most part products of slow going vascular disease of the brain. Glaucoma is nothing but edema of the eye ball due to deficient arterial blood supply to the eye. When vascular disease affects the kidney we have a small red kidney which looks healthy but you will find small spots of gray which are characteristic of vascular disease.

We have been taught in text books that vascular disease goes with a normal or increased water output. The amount of albumin and casts are significant of kidney disease. When an arterio-sclerosis patient comes to you with a normal water output, put it down he has a good kidney. If there are casts and albumin he has a little spot in the kidney. A practical point is that you only need one-half of one kidney to have a normal water output. We have animals that have lived years and years with only one-half of one kidney. Bright's disease is arterio-sclerotic change in the kidney. Bright's original book is the best article I have ever read on the subject. He recognized that the first cause of kidney disease was arterio-sclerotic change. Arterio-sclerosis is due to infection. I do not advocate the use of too much adrenalin in local anesthetics. I believe that bleeding is the thing to do in some cases.

The discussion was led by Dr. Ritchey of the Long Hospital, Indianapolis. Others taking part in the discussion were Drs. Beall, of Fort Wayne; Spurgeon, of Muncie; Marvel, of Richmond; Krebs, of Huntington; Good, of Huntington, nad Sellers, of Hartford City.

Attendance 208.

Adjournment.

R. A. BEESON, Secretary.

THE TRUTH ABOUT MEDICINES

NEW AND NONOFFICIAL REMEDIES

ACNE COMBINED VACCINE-LEDERLE.—A suspension of killed acne bacilli and killed Staphylococcus albus and Staphylococcus aureus. For a discussion of Mixed Bacterial Vaccines, see New and Nonofficial Remedies 1921, p. 314. Acne Combined Vaccine-Lederle is marketed in various size packages containing graduated doses of the vaccine. Lederle Antitoxin Laboratories, New York.—(*Jour. A. M. A.*, Oct. 1, 1921, p. 1103).

PROTOLAC.—A brand of calcium caseinate-N. N. R. For a description of the composition, actions and uses, and dosage, see *Jour. A. M. A.*, Sept. 24, 1921, p. 1023. Dry Milk Co., New York.

BENZYL SUCCINATE-SEYDEL.—A brand of benzyl succinate-N. N. R. For a description of the properties, actions and uses, and dosage, see *Jour. A. M. A.*, Sept. 24, 1921, p. 1023. Seydel Manufacturing Co., Jersey City, N. J.—(*Jour. A. M. A.*, Oct. 8, 1921, p. 1183).

COPPER CITRATE-P. W. R.—A brand of copper citrate-N. N. R. For a discussion of the actions, uses and dosage of copper citrate, see New and Nonofficial Remedies 1921, p. 88. Powers-Weightman-Rosengarten Co., Philadelphia.

MERCURY BENZOATE-P. W. R.—A brand of mercuric benzoate-N. N. R. For a discussion of the actions, uses and dosage of mercuric benzoate, see New and Nonofficial Remedies 1921, p. 192. Powers-Weightman-Rosengarten Co., Philadelphia.

MERCURY CYANIDE-P. W. R.—A brand of mercuric cyanide-N. N. R. For a discussion of the actions, uses and dosage of mercuric cyanide, see New and Nonofficial Remedies 1921, p. 183. Powers-Weightman-Rosengarten Co., Philadelphia.

MERCURY SUCCINIMIDE-P. W. R.—A brand of mercuric succinimide-N. N. R. For a discussion of the actions, uses and dosage of mercuric succinimide see New and Nonofficial Remedies 1921, p. 196. Powers-Weightman-Rosengarten Co., Philadelphia.

SILVER CITRATE-P. W. R.—A brand of silver citrate-N. N. R. For a discussion of the actions, uses and dosage of silver citrate, see New and Nonofficial Remedies 1921, p. 333. Powers-Weightman-Rosengarten Co., Philadelphia.

SILVER LACTATE-P. W. R.—A brand of silver lactate-N. N. R. For a discussion of the actions, uses and dosage of silver lactate, see New and Nonofficial Remedies 1921, p. 334. Powers-Weightman-Rosengarten Co., Philadelphia.

PROCAINE-ADRENALIN HYPODERMIC TABLETS NO. 2.—Each contains procaine-Abbott (see New and Nonofficial Remedies 1921, p. 34) 0.02 gm. (1-3 grain), adrenalin 0.00004 gm. (1-1500 grain) and sodium chloride, sufficient so that when the tablet is dissolved in 1 Cc. of water the resulting solution is isotonic. The Abbott Laboratories, Chicago.—(*Jour. A. M. A.*, Oct. 29, 1921, p. 1423).

PROPAGANDA FOR REFORM

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act, chiefly because the therapeutic claims advanced for them were held to be false: Joyner's Gui-A-Col Compound (William-Ellis Drug Co.), consisting essentially of guaiacol, an iodid, sugar, alcohol, and water, and falsely labeled as a remedy for consumption, whooping cough, and all affections of the throat, chest and lungs. Egyptian Regulator Tea (Kells Co.), consisting essentially of senna, coriander, dog grass, ginger, taraxacum, sambucus, licorice and cinnamon, and claimed to be a speedy relief for dyspepsia, liver complaint, headache and nervousness. Nervosex Tablets (United Laboratories Co.), consisting essentially of strychnine, phosphates, and iron, zinc and calcium salts, and claimed to be a nerve and muscle stimulant. Falsely labeled a compound of nerve and muscle stimulants for low vitality, lack of energy and sexual weakness. Castalian Natural Mineral Water (J. P. Forbes & Co.), recommended for rheumatism, Bright's disease, dyspepsia, diphtheria and other conditions. Man's Capsules (Man's Capsule Co.), consisting essentially of cubebs and copaiba and sold as a remedy for gonorrhea and gleet.—(*Jour. A. M. A.*, Oct. 1, 1921, p. 1119).

PATENT MEDICINES IN ENGLAND.—Broadly speaking, the ethical standards of the "patent medicine" industry in Great Britain in 1921 is that which obtained in the American "patent medicine" industry prior to the passage of the Food and Drugs Act in 1907. As long ago as 1912 the British Parliament created a Select Committee on "Patent Medicines". The Committee published a report in 1914. The coming of the World War favored the nostrum interests and no legislative action was taken until 1920, when a Proprietary Medicine Bill was introduced into the House of Lords. Now comes the Medical Press and Circular (London) complaining that the bill has been pigeonholed. This publication points out that in 1920 the British government received revenue from the sale of "patent medicines" totaling 1,332,661 pounds, and that the very fact that a government hard up for revenue should be able to obtain so vast a sum from a business so largely tinctured with fraud and such a menace to the public health may be "a sufficient reason" in explanation of the British government's attitude of "innocuous desuetude" toward this bill.—(*Jour. A. M. A.*, Oct. 1, 1921, p. 1107).

TOXICIDE NOT ADMITTED TO N. N. R.—The Council on Pharmacy and Chemistry reports that Toxicide (Toxicide Laboratories, Chicago) is alleged to be a remedy which "increases systemic resistance * * * used for immunizing against septic infections * * * is indicated in any case of septic infection, capable of inducing inflammation and pus formation, regardless of location or kind of tissue involved". The manufacturer informed the Council that "Toxicide contains Lachesis 12x, Tarantula 6x, Psorinum (special) 15x, Silica 6x and Excipient q. s. (the excipient is sweet milk) * * * These remedies are combined in the sweet milk and put through a process of development, which produces the curative agent which we call 'Toxicide'." No information was given as to the proportions, either relative or actual, of the ingredients nor was any information given as to the "process of development" to which the mixture is subjected. Neither was any evidence submitted to the Council for the highly improbable claims of curative effect which are made for Toxicide. The Council declared Toxicide inadmissible to New and Nonofficial Remedies because: (1) The identity and amount of the potent constituent or constituents have not been furnished; (2) the preparation is advertised indirectly to the public; (3) the name "Toxicide" is therapeutically suggestive, and (4) the therapeutic claims, being unsubstantiated by evidence, are unwarranted.—(*Jour. A. M. A.*, Oct. 8, 1921, p. 1197).

TIRED RABBITS FOR DIABETES AND RING-TAILED MONKEYS FOR SEX STIMULATION.—In March, 1919, an article by T. Webster Edgar appeared in the *New York Medical Journal* in which Edgar stated that he had treated successfully twenty cases of definite diabetes with intramuscular injections of his diabetic serum. No information was given regarding the serum except that it was prepared from normal blood after the animal is exercised to the point of fatigue. Subsequently newspaper articles appeared in which Edgar is quoted as using the blood of rabbits first placed on a treadmill to produce fatigue. In November, 1920, an article by Edgar appeared in the *New York Medical Journal* on "Sterility, Sex Stimulation and Endocrines" in which he stated that he was interested

Strength and **Pliability** are Found in

Armour Iodized Sheep Gut Ligatures

which are made from lamb's gut selected in our abattoirs especially for surgical purposes.

The **Armour Iodized Ligatures** possess full tensile strength and their pliability prevents breakage at the knot. They are iodized to the core and are absolutely sterile. Regular lengths, sizes 00 to number 4 at $2.50 per dozen.

We also offer **Plain** and **Chromic Ligatures,** sizes 000 to number 4 regular lengths $2.50 per dozen, emergency lengths, $1.50 per dozen (nothing but the smooth side of the intestine is used in the manufacture of the Armour ligatures).

LABORATORY PRODUCTS

Suprarenalin Solution, 1:1000 is stable, uniform and free from preservatives.

Pituitary Liquid is physiologically standardized and is ready for hypodermatic use—½ c. c. ampoules for obstetrical and 1 c. c. ampoules for surgical use.

Literature upon the ARMOUR LABORATORY PRODUCTS for the medical profession only.

ARMOUR AND COMPANY

CHICAGO

Headquarters for the endocrines and other organotherapeutic products.

SAVE MONEY ON YOUR X-RAY SUPPLIES

Get Our Price List and Discounts on Quantities Before You Purchase

HUNDREDS OF DOCTORS FIND WE SAVE THEM FROM 10% TO 25% ON X-RAY LABORATORY COSTS

AMONG THE MANY ARTICLES SOLD ARE

X-RAY PLATES. Three brands in stock for quick shipment. PARAGON Brand, for finest work; UNIVERSEAL Brand, where price is important.

X-RAY FILMS. Duplitized or Double Coated—all standard sizes. X-Ograph (metal backed) dental films at new, low prices Eastman films, fast or slow emulsion.

BARIUM SULPHATE. For stomach work. Finest grade. Low price.

COOLIDGE X-RAY TUBES. 5 Styles. 10 or 30 milliamp.—Radiator (small bulb), or broad, medium or fine focus, large bulb. Lead Glass Shields for Radiator type.

DEVELOPING TANKS. 4 or 6 compartments stone, will end your dark room troubles. 5 sizes of Enameled Steel Tanks.

DENTAL FILM MOUNTS. Black or gray cardboard with celluloid window or all celluloid type, one to eleven film openings. Special list and samples on request. Price includes your name and address.

DEVELOPER CHEMICALS. Metal, Hydroquinone, Hypo, etc.

INTENSIFYING SCREENS. Patterson, TE, or celluloid-backed screens. Reduce exposure to one-fourth or less. Double screens for film. All-metal Cassettes.

LEADED GLOVES AND APRONS. (New type glove, lower priced.)

FILING ENVELOPES with printed X-Ray form. (For used plates.) Order direct or through your dealer.

BALTIMORE

(Continued from page 404)

in sex stimulation and that he had a serum which he was using with success in this condition. During the last year newspapers have carried sporadic reports of alleged remarkable results produced by Dr. Thomas Webster Edgar of New York through the transplantation of "interstitial gland" taken from "a special species of orangoutang". In a letter to a layman Edgar stated that the treatment was successful and that he was now treating all cases by this method, and that the fee for the operation was five hundred dollars inclusive of the sanitarium. Commencing Sunday, Oct. 1, 1921, a series of sensational articles appeared regarding one of Edgar's alleged monkey-gland implantations. The material is played up in the style typical of yellow journalism. The statement that appeared in these articles to the effect that Edgar "is a member of the County Medical Society of New York" is incorrect. Edgar is not a member. The newspaper claim that Edgar is "an authority on glandular transplantation" should be accepted with reservations.—(*Jour. A. M. A.*, Oct. 15, 1921, p. 1272).

PIL MIXED TREATMENT (CHICHESTER).—This is a proprietary preparation of the Hillside Chemical Co., Newburgh, N. Y., sold in the form of pills, each said to contain 1-20 grain of mercuric iodid and 5 grains potassium iodid. The Council on Pharmacy and Chemistry reports that in 1907 the therapeutic claims advanced for the preparation were examined and found to be unwarranted, exaggerated and misleading. Misleading statements were also made for the product itself. The Council holds that the use of Pil Mixed Treatment (Chichester) is on a par with the use of certain blood purifiers which were advocated at a time when the treatment of syphilis was a baffling problem. It reports that the present day advertising, which reads as if it had been written in the heyday of proprietary license, is, in effect, an invitation to treat syphilis in its various stages and manifestations with Pil Mixed Treatment (Chichester). If heeded by those who read the advertising, it will result in much harm to the public and the profession. For this reason the present report of the Council is published as a protest against any advertising propaganda advocating the routine treatment of a disease which requires that each case be studied carefully so that prompt and efficient measures may be applied to the various manifestations of the disease.—(*Jour. A. M. A.*, Oct. 22, 1921, p. 1355).

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act, chiefly because the therapeutic claims advanced for them were held to be false: Euca-Mul (Edward G. Binz Co.), consisting essentially of oil of eucalyptus, sugars, glycerin, gum, water and alcohol, and claimed to relieve bronchial asthma, and to be effective in coughs of phthisis and whooping cough. Kalina Tablets (J. M. Rutkowski and Kalina Co.), consisting essentially of plant extractives, including cascara, aloes, pepper and strychnin, and sold as a health restorer, blood purifier, etc. Howell's Lymphine Tablets (Chas. H. Howell & Co.), pills consisting essentially of ferrous carbonate, nux vomica, aloes and phosphorus, and claimed to relieve all forms of weakness, etc. Wampole's Phosphorus, Nux and Damiana (Henry S. Wampole Co., Baltimore), consisting of the three drugs named, and recommended for impotence, insomnia, hysteria and diseases of the brain of both sexes.—(*Jour. A. M. A.*, Oct. 29, 1921, p. 1438).

CONVERSE TREATMENT FOR EPILEPSY.—An examination of this preparation in the A. M. A. Chemical Laboratory in 1916 showed that essentially each 100 Cc. of the preparation contained about 7.3 gm. ammonium bromid, 5 gm. calcium bromid and 8.7 gm. potassium bromid. Calculating from the bromid determination, each dose of one teaspoonful (1 fluidrachm) contains the equivalent of 14.5 grains of potassium bromide or each daily dose (4 teaspoonfuls) corresponds to 58 grains potassium bromid.—(*Jour. A. M. A.*, Oct. 29, 1921, p. 1440).

MICAJAH'S UTERINE WAFERS.—Micajah's Medicated Wafers (formerly called Micajah's Medicated Uterine Wafers) were analyzed in the A. M. A. Chemical Laboratory in 1910, and found to consist essentially of dried "burnt" alum, boric acid and borax. In 1919 the Council on Pharmacy and Chemistry in reporting on this product showed that whatever virtues might be possessed by the proprietary are those inherent in such well known astringents as alum, boric acid and borax. Micajah's Medicated Wafers are an excellent example of mischievous proprietary medicines. Physicians who use this will be likely to overlook or pass over new growths, specific infections and diseases that require radical remedial measures.—(*Jour. A. M. A.*, Oct. 29, 1921, p. 1441).

SAL HEPATICA.—Little information is given, or apparently ever has been given, by the proprietors (The Bristol-Myers Co.), in regard to the composition of Sal Hepatica. Some years ago medical journal advertisements contained the statement that it contained all the "Tonic, Alterative and Laxative Salts of the celebrated 'Bitter Waters' of Europe * * * fortified by the addition of Lithium and Sodium Phosphates". It has also been claimed that Sal Hepatica is "a saline combination with the addition of Sodium Phosphate and Lithia Citrate".

The label of a recently purchased specimen contained the declaration, "Sal Hepatica is an effervescent saline combination possessing medicinal properties similar to the natural 'Bitter Waters' of Europe, and fortified by the addition of Sodium Phosphate". In view of these indefinite statements the A. M. A. Chemical Laboratory made an analysis of the product. The analysis showed it to have the following composition: Sodium phosphate anhydrous 4.4 percent, sodium sulphate anhydrous 26.5 percent, sodium tartrate anhydrous 12.7 percent, sodium bicarbonate 19.5 percent, tartaric acid (free) 20.8 percent, sodium chloride 8.9 percent, lithium phosphate trace, water of hydration (by difference) 7.2 percent. Sal Hepatica, therefore, is essentially an effervescing mixture of dried sodium sulphate and sodium tartrate with a little dried sodium phosphate and table salt added. Sal Hepatica, then, is a simple effervescent saline laxative. It is essentially secret in composition and is sold under claims that would be laughed at were the full formula of the product a matter of public knowledge.—(*Jour. A. M. A.*, Oct. 29, 1921, p. 1438).

A certain little girl, convalescing from a childish ailment, wanted something to eat, and as is usual with little people, wanted it at once, she demanded it again in an imperative voice.

"Wait a moment, you little impatient!" nurse answered.

"I ain't a him-patient," was the indignant retort. "I'm a she-patient."—*London Answers.*

"Oh, Freddie, don't you think you've had enough ice cream?" asked Aunt Mary, after helping him a second time.

"No; I don't feel sick yet."

Aaron Diseases of The Digestive Organs

New (3d) Edition
WITH SPECIAL REFERENCE TO DIAGNOSIS AND TREATMENT

"THE PHYSIOLOGY OF DIGESTION has been considered from *the viewpoint of the clinician* rather than from that of the physiologist."—This significant line occurring in the preface is indicative of the basic plan of the entire work. Throughout, it is *the clinical side* that is emphasized. Dr. Aaron was a pioneer in this field, his literary and professional activities for some thirty years playing no little part in bringing this specialty to the forefront of interest. The book reflects this ripe experience.

Incorporated in this work is *everything in the diagnosis and treatment of digestive diseases* known and approved by medical science. Sound clinical practice is found on every page. The technic of the many diagnostic tests and reactions and the use of the various apparatus and instruments employed both for diagnostic and therapeutic measures, are given in every case. Another feature is the many prescriptions given under the various diseases. The plan of the book enables you to find the desired information in a moment, for following the physiologic path of the digestive tract, it takes up in orderly succession the diseases of the MOUTH, PHARNYX, ESOPHAGUS, STOMACH, LIVER, GALL-BLADDER, BILE-DUCTS, PANCREAS, SMALL INTESTINE, VERMIFORM APPENDIX, CECUM, COLON, SIGMOID FLEXURE, RECTUM AND ANUS.

This edition is 86 pages larger than the last, and contains a number of new colored plates, roentgenograms and engravings. Of the wealth of new material, particular attention should be called to—the STOMACH TUBE and the qualitative and quantitative analyses showing the actual condition of the gastric functions—the tests and reactions for the diagnosis of CARCINOMA—the new and important applications of the DUODENAL TUBE in diagnosis and the technic of *non-surgical biliary-tract drainage* to remove biliary stasis, eliminate infection and reduce gall-bladder and bile-duct inflammation. New methods of EXAMINING THE FECES are given, also the TEST DIETS and the TEST-DIET STOOL FINDINGS *in each one of the diseases of the digestive organs.* To the ROENTGEN RAY a special chapter is devoted. There is much new matter on DIETETICS, a full dietary being given for each digestive disorder. HYDROTHERAPY, MINERAL WATERS, MASSAGE AND ELECTRICITY are fully covered. Recent advances in the diagnosis and treatment of the diseases of the ESOPHAGUS are presented. There is a full discussion of NEUROSES resulting in motor, sensory, or secretory disturbances. The *quinine and urea injection treatment that has revolutionized the treatment of internal hemorrhoids* is given in detail.

To sum up, the many new methods of investigation, *physical, chemical microscopical,* and *clinical,* have given greater certainty in dealing with obscure pathologic processes. This work *covers them all and gives every needed detail.*

By CHARLES D. AARON, Sc.D., M.D., Professor of Gastro-enterology and Dietetics in the Detroit College of Medicine and Surgery; Consulting Gastro-enterologist to Harper Hospital. Octavo, 904 Pages, with 164 Engravings, 48 Roentgenograms and 13 Colored Plates. Cloth, $10.00 net.

ULCER OF THE STOMACH AND DUODENUM

ETIOLOGY AND PATHOLOGY*

B. W. RHAMY, M.D.
FORT WAYNE, INDIANA

Simple ulcer of the stomach was first described by Cruveilier in 1830 and his description serves admirably today.

Ulcers are usually solitary, may occur in any portion of the stomach, but are usually found at the points subjected to the greatest irritation; namely, in the lesser curvature, in the posterior wall, and near the pylorus. Ulcers may be round, oval or irregular and vary in size from a pin head to a pancake. They may have a superficial saucer shape, be a deep irregular funnel, or a clean punched out hole. Occasionally one is found with the large end of the funnel toward the peritoneum. The edges in acute ulcer are soft but in the chronic type are indurated as the result of inflammatory and scar tissue. The mucous membrane around them may be reddened from inflammation while the rest of the stomach shows a chronic catarrhal inflammation. The exposed surface of the ulcer is usually a grayish brown from changed blood and the replacement fibrosis brought about by the constant tendency of the ulcer to heal. Commencing in the mucous membrane, ulcers gradually extend through the coats of the stomach and in this process blood vessels are eroded, causing more or less severe hemorrhages.

Finally, the peritoneal coat may be perforated, causing peritonitis. Nature attempts to block this process through localized peritonitis which forms protective adhesions, tending to plug up any perforations with some contiguous abdominal structure, usually the pancreas or liver. This contiguous structure then becomes the base of the ulcer; and in turn, may be penetrated by the ulcerative process, producing abscess, inflammation and fistulæ. Instances have occurred where the bowel, being the structure plastered to the ulcer, has been perforated, forming a natural gastro-enterostomy. According to Brinton, adhesions to adjacent abdominal organs occurs in about 40 percent of cases, and perforations in about 13 percent. Over half of all ulcers heal spontaneously, forming dense scar tissue, which is not only apt to be the seat of new ulceration, but to produce marked deformity in the form of pyloric obstruction, or hour glass stomach, depending on the location. In such recurring ulcers the tendency to hemorrhage and perforation is greater than in the primary ulcer.

Statistics give the site of peptic ulcers about as follows: In the lesser curvature about 30 percent, the posterior wall 38 percent, at the pylorus 16 percent, in the anterior wall 6 percent, at the cardia 4 percent, the fundus 3 percent and in the greater curvature 3 percent. As to the frequency, between 4 and 5 percent of all postmortems show healed or unhealed peptic ulcers, of which about 80 percent are solitary and about 20 percent multiple. Howard analyzed the statistics of 161,599 patients treated in American hospitals and found 930 instances or .57 percent in which ulcer was present. Statistics from European hospitals give about 1.3 percent. Duodenal or juxtapyloric ulcers, *i. e.*, those occurring within 1½ inches of the pylorus or above the opening of the common duct, must be considered as peptic ulcers, since they are bathed by unchanged acid chyme before it is neutralized by the alkaline secretions in the duodenum. Peptic ulcers are found beyond the pylorus at least twice as frequently as in the stomach. The Mayo Clinic in 2,500 cases operated, found duodenal ulcers 73 percent to stomach ulcers 23 percent. Males are more susceptible than females in about the proportion of 4 to 1. The ulcer age is between 17 and 40 years, although ulcers of the acute type have been found in children, even in very young babes, Gargot reporting one in a babe 30 hours after birth. Cackovic in 172 operative cases found 2.32 percent who were under the age of 10 years.

*One of the papers of a symposium presented before the Indiana State Medical Association, Indianapolis Session, September, 1921.

Etiology. Obviously the normal gastric mucosa is naturally resistant to normal gastric juice, indeed it may be accepted as true that almost any *living* tissue possesses the power of resisting digestion, probably by means of antiferments, and that this power is most in evidence in the gastric mucosa. The essential pre-ulcer change, therefore, must be one that either renders a localized area of mucosa abnormally susceptible to the action of acid gastric juice, or one that causes necrosis and sloughing independent of any action of the gastric juice. Among the most important possible etiologic factors about which theories have been built are: the effect of long continued trauma from coarse foods, coupled with the action of acid gastric juice, impaired blood supply, impaired nerve supply, and bacterial infection.

Vascular Factors. In favor of the vascular origin has been mentioned the localized punched out character of ulcers as indicating either a localized thrombosis or an endarteritis obliterans with necrosis and digestion of the resulting infarct. Ulcers as the result of thrombosis have been produced experimentally in animals by the injection of chemicals into the small blood vessels of the stomach. On the other hand, it has been pointed out that in youth, where ulcers have formed as the result of infection and embolism, they were of the acute type and healed readily. Microscopic examination of the blood vessels immediately adjacent to an ulcer frequently shows occlusion by thrombosis and endarteritis, but again, as these pathologic changes are always found in an ulcerative process, they must be regarded as most apt to be of the secondary variety, *i. e.*, protective thrombi, etc. Reeves, *Surg. Gyn. and Obst.* Apr. 1920, found that in the area of predilection for ulcer formation, *i. e.*, on both sides of the pylorus, the blood supply is not as free as in other parts of the stomach, as the arteries are fewer in number, smaller, longer and make fewer anastomoses. He advanced the idea that these circumstances make an occlusion of one of these vessels a more important factor in the production of ulcer than if there were free anastomosis.

Nervous Factors. Ulcer of the stomach has been induced experimentally through interference with the nerve supply, by section of either the vagus, sympathetic, or the spinal cord. As ulcer is associated with spasms of parts of the stomach, it has been argued that this nerve section caused localized anemia, by spasm of smooth muscle compressing the arteries of the mucosa. Reflex irritation of the nerves of the stomach from appendicitis or other abdominal diseases has also been advanced as a possible cause of ulcer. Hurst believes that the association of chronic appendicitis with gastric and duodenal ulcer is too common to be a coincidence; and that the greatly diminished tendency to relapse, especially of acute ulcers, following removal of the appendix, but without interference with the ulcer, proves the appendix to be the primary condition. He is also convinced that excessive smoking, through its effect on the autonomic nervous system, by increasing hypertonus and inducing hypersecretion, promotes ulceration. It is, however, a mooted question as to whether appendicitis might cause ulcer by reflex nerve irritation, or as a primary focus of infection.

Hurst is convinced that "it is a peculiar type of stomach or duodenum that develops ulcer, since the primary causes of irritation do not commonly affect the normal stomach". It seems possible that just as one type of individual may have epilepsy and another migraine, so still another type may be subject to peptic ulcer. Wolff, in *Hygea-Stockholm* Aug. 21, 1920, refers the symptoms of peptic ulcer, *i. e.*, pains, gastro-spasm, hypersecretion and contraction of the mucous membrane and its blood vessels, as a manifestation of overactivity of the vagus nervous system, and suggested the use of atropin. Von Arnstel has reported 50 cases in which .5 to 1 mg. of atropin sulphate was given daily for 10 weeks with marked diminution of the symptoms. Moynihan noted in his patients that attacks were more frequent and prolonged in winter and were brought on by dietary indiscretions, overwork, worry and exposure, all of which might act through the nerves or by lowering the general resistance.

Trauma. In considering the effects of trauma from foods, etc., it may be said that ulcer is extremely rare compared with the frequency of the exciting causes, which argues that injury is unlikely unless the vitality of the mucosa is already lowered by some means. The following points stand out in reference to trauma: Ulcers are prone to appear in the lower end of the stomach, which is the most active part, longest in contact with the acid chyme and longest subjected to irritation of partly digested and irritating foods, such as alcohol, vinegar, fruit acids, mustard, peppers, seeds, skins and fibres of nuts, fruits and vegetables passing into the duodenum. Abrasions, erosions or acute ulcers may form in consequence, and these same factors of irritation would tend to prevent healing, making chronicity possible. Bacterial infection of such damaged tissue probably always occurs and this in turn would cause congestion and edema, further factors favorable to devitalization. Such devitalized infected tissue would afford little resistance to digestion. Barcley and Hurst, *Brit. Med. Jour.* Apr. 24, 1920, in experiments on animals, found that an exposed acute ulcer would heal in from 12 to 20 days,

but by rubbing them daily with coarse foods such as might go into the stomach, they prolonged the healing to from 30 to 52 days in 11 cases so treated.

Of interest in discussing the possibility of trauma in the etiology of peptic ulcer is the discussion by Terry, *Jour. A. M. A.* July 24, 1920, on ulcers of the jejunum following gastro-enterostomy in which the primary cause is ascribed to trauma by instruments, non-absorbable sutures and buttons, the tissue thus traumatized being digested by the acid chyme. Improper food and insufficient mastication are common faults and may early in life begin to pervert the functions of digestion and set up chronic gastritis with stasis of the lymphatics. It is possible that this early abuse of physiologic function may lay the foundation for ulcerative processes.

Barcley and Hurst found that the stomach in duodenal ulcer was hypertonic, *i. e.*, hanging high up and consequently emptied rapidly, so that the first part of the duodenum was constantly in contact with exceptionally acid juice. In gastric ulcer, the stomach was hypotonic, *i. e.*, hung low, and in consequence emptied slowly, the acid chyme remaining long in the stomach and only a little at a time going into the duodenum.

Hyperchlorhydria in Ulcer. The conception of hyperchlorhydria as the primary etiologic factor of peptic ulcer has long been prevalent. Moynihan at one time promulgated the rule that chronic hyperacidity was in practically all cases a definite indication of ulcer. Recently much experimental laboratory and clinical evidence has been offered to disprove this principle, the most radical being that hyperacidity was either a complicating incident or was secondary and due to reflex irritation from the ulcer or its products. That there is a relationship between hyperacidity and ulcer is shown first by the fact that hyperacidity is the rule in peptic ulcer, and second by the fact that the majority of round ulcers occur in areas most exposed to acid secretions, namely, on either side of the pylorus.

Although hypo-acidity has been found in ulcer and conversely hyperacidity in non-ulcer cases, from my own observation I would suggest that many of the cases showing hypo or anacidity probably had a hyperacidity in the pre-ulcer period. In practically all cases of ulcer coming under my observation, hyperacidity was a prominent symptom, and when hypo or anacidity was present, history of previous hyperacidity could be elicited. The pathologic changes as I see them are these: first a chronic hyperacidity during the formative stage of the ulcer. In the course of years of a continuous or recurrent ulcerative process, the continued irritation, indurative inflammatory processes, etc., with the accompanying gastritis, may gradually bring about a loss of gastric function characterized principally by reduction in the acid content of the gastric juice. This stage of hypo or anacidity I consider to be a pre-cancer stage during which the ulcerative process is very apt to be transformed into a malignancy.

Smithies, *Jour. A. M. A.*, June 5, 1921, says experimental introduction of high acid values, even as much as ten times the normal amount, failed to damage the normal mucosa, and quotes Carlson "that introduction of acid in cases of ulcer does not produce clinical discomfort". As to the value of this observation I have serious doubts, first because a few introductions of acid cannot be compared to the insidious effect of the long continued and constant irritation of hyper acid gastric juice, and second in my own experience it has been an observation common to all ulcer cases that they avoided acid foods on account of discomfort. In Smithies's records of 2,168 proved ulcers, 33.4 percent had hyperacidity, 41 percent normal acidity, 23 percent subacidity and 2.6 percent anacidity. Eggleston, however, *Jour. A. M. A.*, Dec. 4, 1920, in 500 cases found 73 percent having hyperacidity, 14 percent normal acidity, 11 percent hypoacidity and 2 percent anacidity, while Gongolez, *Siglo Medica Madrid,* May 1, 1920, in 715 positive cases of ulcer noted 96.2 percent with hyperacidity. He claimed that the treatment which cures ulcer also cures hyperacidity, and that this is a further argument in favor of the association of hyperacidity and ulcer. From these figures it can be safely concluded that at least the majority have hyperacidity. The fact that in perforated ulcers plastered up by some adjacent organ like the liver, the ulcerative process may extend into this adjacent tissue, is in my mind proof conclusive that the eroding action is digestive in character.

Cellular Toxins. Brief mention may be made of the theory of cellular toxins. Turck has stated (see Lewishon, *Jour. A. M. A.*, Aug. 6, 1921) that by causing tissue breakdown in animals, tissue toxins were liberated, causing the development of ulcers in 36 cases. This he thinks was brought about when the animal, losing its protective power against its own tissue toxins, a stasis in the blood vessels of the mucosa occurred. Jona, *Med. Jour. of Australia,* March 2, 1918, prepared extracts of burnt tissues using liver, placenta, spleen and muscle tissue and injected these extracts into animals. He concluded that these injections caused inhibition of gastro-intestinal secretions, and believed this to be a potent factor in the causation of duodenal ulcers after burns.

Theory of Bacterial Infection. The infectious origin of ulcer has had advocates for many

years. Experimentally ulcer has been produced by intravenous injections of pus, of bac. pyocyaneus, bac. dysentery, bac. coli, lactic acid bacillus, pneumococcus, staphylococcus and streptococcus. Rosenow, *Jour. Inf. Dis.,* September, 1918, has reported a strain of streptococcus which he claimed has an elective localizing affinity for the mucosa cells, the injection of which produced chronic ulcers. Bacteria of various kinds have been found in ulcer walls, and as the initial lesions of ulcer are localized necrosis, localized hemorrhage and inflammation of the lymph follicles, it has been pointed out that the common cause of local necrosis anywhere is bacterial infection, acting either locally or by means of their toxins in the blood stream, which by destroying the endothelial cells of the capillaries pave the way for the local destructive action.

Infection of one or more of the lymphatic follicles so thickly studded along the lesser curvature, especially toward the pylorus, may give rise to a sub-mucous abscess which by rupture allows the gastric juice to act on the base of the ulceration thus exposed. Clinically, ulcer has been noted in connection with various infective processes, as diseased tonsils, infected appendix, gall bladder infection and infected teeth. Rosenow believed germs from an infected mouth affected the stomach mucosa by way of the blood stream rather than by swallowing. As variations of the theme of infectious origin Askanazy, *Revue Medicale de la Suisse Romande-Geneva,* August, 1920, found the fungus oidium albicans constantly present in his ulcer cases, and noted in his experiments that this fungus grows best in acid media. To this fungus he ascribes the infection and advises combating the infection and thus curing the ulcer by neutralizing the acid favorable to their growth. Mongorge, *Lyon Medical,* May 25, 1920, on the ground that Jaksch and Brinton have asserted, that 25 percent of ulcer cases die of tuberculosis; and assuming that ulcer is a toxic-infectious disease; and as tuberculosis is the toxi-infectious disease par excellence, therefore he argues, round ulcer must be often of tuberculous origin. He cites ten cases of this kind.

The Role of Syphilis in Peptic Ulcer. It is rather surprising how little attention has been given to syphilis in the study of diseases of the stomach. Only within the last three or four years has serious attention been given to this problem, authorities having previously passed the subject by with the brief statement that syphilis of the stomach was rare. The prevalence of lues and its widespread activities throughout the body make it manifestly an impossibility that the stomach should escape damage. Furthermore, it is an erroneous idea to conceive syphilis of the stomach only as a gummatous lesion, for it is a well known fact that the spirocheta pallida is a connective tissue parasite, and since the walls of the stomach contain much connective tissue, interstitial inflammation is possible.

Syphilis of the stomach, as one writer remarks, forms a fascinating problem, there being no clear cut symptomatology and no certain clinical findings to differentiate luetic gastric lesions from any other. The diagnosis can only be made by exclusion, and therefore no examination of gastric disease is complete that does not consider syphilis and include a Wasserman test. By so doing, within the last three or four years, more cases of syphilis of the stomach have been reported than had been previously in the history of medicine. There are two ways in which syphilis may affect the stomach: first, by a definite lesion in the form of a gumma, or an interstitial inflammation; and, second, as a part of a widespread manifestation such as arterio-sclerosis or disease of the nervous system. Therefore, although it is possible for a patient to have syphilis and his stomach not be luetic, yet if definite improvement of the gastric condition occurs under luetic treatment, it can be safely assumed that it is of luetic origin, especially if ordinary treatment had previously failed. Syphilitic ulcers of the stomach have in the past been conceived only as broken down gumma, yet there is no reason why syphilis cannot, through an endarteritis obliterans, an arterio-sclerosis, or a degenerative process in a nerve ending, produce a localized devitalized area subject to digestion by gastric juice, in the same manner as has been ascribed to other infectious organisms.

Smithies, *Am. Jour. Syph.,* January, 1917, describes syphilitic infection of the stomach wall first as a dense round cell infiltration of the loose areolar tissue. From this, four types of lesion may develop, (1) diffuse infiltrations causing thickening of the wall, (2) localized dense round cell groupings which may end, as miliary gummas, or coalesce, necrose and slough forming ulcers, (3) inflammatory nodules producing definite tumefaction, and (4) parigastritis with adhesions. The clinical manifestations from these pathological variations would be chronic gastritis, ulceration, tumor and perigastritis. Smithies reports 34 cases of gastric disease with positive Wassermans, of which 18.2 percent were found to have gastric ulcer and 41 percent duodenal ulcer. Other observers report anywhere from 3 percent to 10 percent of their gastric cases as luetic. In my laboratory I have definite records of 55 cases of peptic ulcer, of which 16 or 29 percent showed positive Wassermanns and responded to anti-luetic treatment.

Two other cases which gave two negative Wassermanns also responded to anti-luetic treatment.

Conclusion. A study of the literature on these various theories brings out the startling fact that each theory has been definitely proven by laboratory and clinical experiments. Summing all the evidence up one might draw the conclusion that whatever experimental means was used the general result was a *lowered resistance,* and that coarse foods and the gastric juice did the rest.

Most writers agree that two factors enter into the etiology: first, there must be a localized loss of vitality or resistance, whether it be circulatory, traumatic or trophic, and whether these disturbances be caused by bacteria, hyperacidity, spirocheta pallida or toxins; and, second, that given such a vulnerable area of mucosa, an active gastric juice, usually but not necessarily hyperacid, brings about the formation of peptic ulcer by its digestive action.

Peptic ulcer is then a local disease brought about by a systemic disturbance causing local manifestations including lowered resistance, and blood stasis; second, the irritation of coarse foods abrading the devitalized area; and, third, the corroding action of the gastric juice.

Finally, in studying an individual case, all these factors must be kept in mind, particularly syphilis, and no examination of any gastro-intestinal lesion should be considered complete without a Wassermann test. When the time arrives when this has become a routine part of the examination, the statistics, in my opinion, will show a marked increase in luetic percentages.

ULCER OF THE STOMACH AND DUODENUM

DIAGNOSIS AND TREATMENT*

W. H. FOREMAN, M.D.
INDIANAPOLIS, INDIANA

The upper end of the gastro-intestinal tract from cardia to jejenum, including bile passages, liver and pancreas, are closely related embryologically, and are richly supplied with splanchnic and vagus fibers, so that irritating lesions in any of these structures would readily modify the function of those portions most active and most subject to change, viz., stomach and duodenum.

For the same reason the stomach and duodenum are very susceptible to functional or organic disturbances in other portions of the tube, and in other viscera, and to reflexes physical, nervous or psychic. Likewise because of their embryological development in the center of the abdomen, the mind refers visceral pain to the midline, besides, from early childhood we have been taught to localize abdominal pain in the "stomach". These facts may explain the very common localization of abdominal visceral pain in the epigastrium, and the similarity of visceral symptoms in gastric and duodenal ulcer and in lesions of the bile ducts, liver, pancreas and other viscera, and in reflex influences.

While the ordinary somatic stimuli applied to the viscera and to visceral lesions are not adequate to produce the sensation of pain in the viscera, yet the natural stimulus to which the viscera are subjected, viz., adequate tension, or distension plus tone, produces a sensation of fullness if a certain degree of tension is slowly produced, or the sensation of pain if the same adequate tension is rapidly produced. It would thus seem that the stimulus for visceral distress or pain is adequate tension on the fibers of the muscular coat of hollow organs, or on the capsule of solid organs.

The same reasoning would suggest that gastric or duodenal ulcer symptoms are not due to direct mechanical or chemical irritation of the ulcer, but to intrinsic neuromuscular changes in gastric and duodenal irritability, rhythmicity, contractility and tone due to the influence of the ulcer on local metabolism, or reflex through extrinsic vagus and splanchnic nerve control.

In disease, and especially visceral disease, the cerebro-spinal nerve centers may become hyperirritable from constant amplified stimuli, so that their threshold of response is lowered, and impulses which are normally unnoticed may penetrate the nerve synapses and reach consciousness and be expressed as altered sensation (fullness, distension, hyperesthesia or pain) in visceral or somatic structures, and more especially does this occur in the epigastrium.

Nerve exhaustion from overwork or from too constant application as in the overzealous business or professional man, or the physically exhausted nervous woman, or from worry over business, health or domestic affairs, produce altered nerve response with symptoms frequently referred to the epigastrium.

Gastric sensibility and pain are largely influenced by nerve and psychic stability and irritability. The unstable, fatigued and irritable nerve centers of the neurasthenic are conducive to variable and magnified gastric sensibility. The perversions of interpretation of sensory stimuli as occur in the hypochondriac lead to various subjective symptoms of epigastric distress or pain. Apprehension, suggestibility and fear markedly influence gastric sensibility. Emotional and hysterical individuals often suffer with subjective gastric distress.

As functional disturbance of the nerve and psychic centers result in altered nerve response

*One of the papers of a symposium presented before the Indiana State Medical Association at the Indianapolis Session, September, 1921.

to stimuli in such a manner as to modify or produce gastric symptoms, to a greater degree does organic disease of the nerve centers modify nerve and psychic response to stimuli. Thus it is that the pain of a locomotor ataxia is referred to the epigastrium.

Again the antagonistic action in the viscera of the two divisions of the vegetative nervous system, the one activating and the other inhibiting action, maintains visceral equilibrium. When this equilibrium is disturbed by over-irritation of either system, a disturbance in function ensues and symptoms result manifested in disturbances of gastro-intestinal motility, secretion and sensation.

Acute pain, toxemias, acute infections or strong emotions stimulate the sympathetic nerves and inhibit gastro-intestinal tonus and spasm (sympathicotonia) while continued irritation, chronic inflammation (with but little toxemia), neuroses and anaphylactic states, stimulate the parasympathetic system and activate gastro-intestinal tonus and spasm often adequate for distress or pain (vagotonia). We also must remember that the sensibility of the two systems, while essentially unlike in different individuals, also is variable in the same individual.

Another confusing element is the epigastric or gastric distress and pain from disease or dysfunction in other viscera or other structures. This is well exemplified in acute appendicitis, where the earliest pain is visceral and is located in the midline in the region of the umbilicus (referred pain).

It is possible that the visceral stimuli may be sufficiently strong and persistent, or the threshold of nerve response amply lowered to induce viscerosensory, visceromotor or viscerosecretory reflexes adequate for true or reflex gastric distress or pain, which may accompany the "localized" pain, although their differentiation may be exceedingly difficult or impossible. Or the irritation from the diseased appendix may induce intrinsic neuromuscular irritability, contractility and tone in the stomach adequate for gastric distress or pain.

Simultaneous with this pain, or subsequent, is the pain, hyperesthesia and hyperalgesia in somatic structures supplied by spinal sensory nerves, which arise from the same spinal segment or segments to which the afferent sympathetic fibers which supply the appendix pass. The breadth of this reflex depends upon the strength of the afferent sympathetic stimuli and nerve cell resistance in the cord. The afferent impulse may be transferred to more widely spread efferent neurons, making the area of reflex response greater.

In a similar manner do diseases or disturbances of other viscera produce these types of localized, true or reflex visceral pain. Angina pectoris is frequently diagnosed as "acute indigestion", chronic appendicitis or cholecystitis as "stomach trouble"; bowel distress or pain is frequently localized in the epigastrium; in pulmonary tuberculosis the symptoms are often gastric; pelvic or renal diseases often produce stormy gastric symptoms of nausea, vomiting and gastric distress or pain, while the symptoms of functional or organic nervous and psychic disturbances are frequently manifested in the stomach.

The effect of exposure in the production of colds is a common observation, the afferent impulses pass over the spinal sensory nerves, the efferent over the sympathetic nerves which influence vascular and visceral tone. Disease in somatic structures may similarly influence vascular and visceral tone. Exposure may produce a pleurisy, bronchitis or pneumonia, equally so may it disturb gastric or intestinal function. The vascular and visceral insult and decreased tissue resistance even producing acute inflammation with dull ache or acute pain and if persistent chronic inflammatory changes with corresponding modified function.

In like manner we may have gastric symptoms as a result of intoxications, or diseases of metabolism, of the blood and ductless glands. The epigastric pain of chronic lead poisoning or of the morphine habitue, the distress or pain in the epigastrium in anemia, chlorosis, diabetes and obesity are examples. The opposing action of pituitrin and adrenalin on unstriped muscle, the influence of over and under activity of the gonads, thyroid and parathyroids must always be considered. Not a few cases are operated for appendicitis, tubal, ovarian or gall-bladder disease, or treated medically for colitis, spastic bowel, gastritis or gastric or duodenal ulcer, when the real trouble may be an overactive pituitary or thyroid or under active adrenals, gonads or parathyroids.

It may thus appear evident that gastric symptoms simulating ulcer may be due to so many factors outside the stomach, its walls and orifices, that we are not justified in diagnosing organic disease in the stomach or duodenum from gastric symptomatology. However, there are certain differential facts or tests which may aid us in determining the nature and source of gastric symptoms.

The history and clinical symptoms of gastric and duodenal ulcer are so distinctive, as Moynihan has pointed out, that the diagnosis might be made by correspondence. This may be true of typical ulcers, but unfortunately most ulcers are atypical in their symptomatology, and this is even more true in gastric ulcers, besides the greater percent of all gastric symptoms are functional and simulate those of organic gastric

or duodenal disease, so that the differential diagnosis requires the closest study, observation and analysis.

The ordinary typical ulcer history as understood is only a hyperacidity history and any condition giving rise to hyperacidity may simulate ulcer. On the other hand, ulcer may exist without hyperacidity, with normal or subnormal acid values, and thus without presenting the familiar typical history we have learned to expect. The vomiting of blood is not a common incidence in ulcer, and even the presence of blood in the vomitus, aspirations or stools is not conclusive of organic gastric disease unless extraneous sources are excluded, besides hematemesis may occur in association with hyperchlorhydria from any cause, when no ulcer or other organic disease exists. The ready relief of gastric pain by food, alkalies, aspirations and lavage if methodical and complete is good evidence of ulcer, and yet I have many times seen bowel or hunger distress relieved by the same means. The evidence of seasonal remissions, recurrences and chronicity seem conclusive, and yet in my experience some of the most typical chronicity ulcer histories have been cases of chronic pulmonary tuberculosis in which the added vasomotor insult due to weather changes during the spring and fall months reduced tissue resistance and induced sufficient acute pulmonary inflammation for reflex recurrence of gastric symptoms.

The entire absence of any gastric abnormality except subjective tenderness in the epigastrium or in one or the other hypochondrium on physical examination has long been assumed to be characteristic of ulcer, especially when history has created the impression that ulcer exists. A palpable tumor in the epigastrium is rarely due to cicatricial tissue of a chronic ulcer. When found it is usually a neoplasm. The discovery of peristaltic waves across the stomach means mechanical obstruction, with hypertrophy and tone of the gastric walls; but it does not by itself indicate ulcer any more than it does cancer, or adhesions, or possibly lesions in other viscera or structures. The value of the physical examination is the negative or positive findings in other viscera and structures, for we now know that various extragastric conditions may present a symptomatology similar to gastric or duodenal ulcer.

Too much reliance in the past has been placed on the analysis of gastric contents. The characteristic finding was hyperacidity; and when this was proved to exist, "after a typical ulcer history had been elicited and a tender spot in the epigastrium had been found, the last bit of evidence was supposed to have been adduced to justify a diagnosis of ulcer." It is true that hyperacidity accompanies ulcer, on the contrary ulcer is almost as frequently found with acidity within normal limits or even below normal, while hyperacidity may be associated with numerous other conditions besides ulcer. Hence the old diagnostic combination of characteristic history, negative gastric physical findings, and hyperacid stomach contents may mean ulcer or various other conditions.

A common symptom in gastric or duodenal ulcer is hypermotility. The explanation probably lies in disturbance of local metabolism from mechanical or chemical irritation of the ulcer, resulting in intrinsic neuromuscular changes in gastric and duodenal irritability, rhymicity, contractility and tone; or to reflex influences on gastric and duodenal motility and tone through extrinsic vagus and splanchnic nerve control, the fibers of which are plentifully supplied to the upper gastro-intestinal tract from cardia to jejunum. This increased gastric motility and tone is usually accompanied by inhibition of pyloric relaxation, due to increased gastric acidity, amounting often to pyloric spasm, and delay in gastric emptying often sufficient to suggest mechanical obstruction, or the mechanical obstruction may be due to induration or cicatricial scar from chronic recurrent ulcer. But here we must also remember that similar disturbances in gastric motility and emptying may be due to cancer, or to lesions in other portions of the gastro-intestinal tract or in other viscera, which produce increased gastric acidity, or inhibition of pyloric relaxation and gastric motor irritability.

The fluroscope is of inestimable value in the study of gastric motility and gastric emptying. The fluorescent screen enables us to study gastric waves, their number, rhythmicity, depth and the manner in which they fade away at the contraction ring; also the duodenal cap, and the rapidity of gastric and duodenal emptying. In case fluoroscopic examination suggests crater or puckering deformity or motor interference, roentgenograms are indicated for detail and graphic record. It should be remembered, however, that anatomical defects may not show in the roentgenograms if they be on the posterior aspect of the stomach or duodenum as frequently occur, or on the anterior surface as occasionally happens, or unless the defect is placed in proper perspective, or the stomach properly distended by the barium meal.

We have learned, if no evidence of ulcer appears from the fluoroscopic or roentgenographic examination, to distrust all other evidence, no matter how convincing it may appear. On the other hand disturbed motility or retarded gastric or duodenal emptying, or apparent defects in the outlines of the pylorus, duodenal cap, antrum, fundus, or greater or lesser curvatures, suggesting the presence of ulcer, should

not be interpreted as positive proof unless other evidence coexists in history, physical examination, laboratory findings and clinical test outs. This whole question of the results obtained by gastro-intestinal roentgenographic examinations is a very serious one, for no man can devote his time both to clinical investigation and to roentgenographic technic without doing injustice to one or the other, and roentgenographic evidence is misleading and worthless unless taken in connection with the history and physical examination, laboratory and clinical findings.

The majority of stomach ulcers that are located on the lesser curvature or posterior wall, and distant from the pylorus, usually give rise to few symptoms and heal without treatment.

No doubt pyloric and duodenal ulcer symptoms disappear under various treatments, medical or surgical, or without any treatment. Many cases presenting symptoms of gastric or duodenal ulcer are not ulcer, but temporarily respond to any treatment which offers rest, restricted diet and better drainage, symptoms recurring again under like conditions. Likewise all ulcer cures, medical or surgical, are not cures, only symptoms are relieved, the ulcer does not heal.

The fundamental questions in the treatment of ulcer as stated by Sippy are: (1) What retards or prevents ulcer healing; (2) What can we do to promote best the development of granulation tissue essential to the healing and final cicatrization of ulcer; (3) What procedure is best to prevent and relieve complications?

It has been proven that a small amount of free hydrochloric acid in the stomach is just as potent in activating the pepsin as a high degree of acidity, also that while acid gastric juice may not be the cause of peptic ulcer, yet it is usually present in varying amounts in active ulcer, and inhibits or prevents ulcer healing either by its corrosive action, or by its influence on gastric hypertonus, peristalsis and pyloric inhibition, preventing gastric and duodenal rest so necessary to ulcer healing.

It would therefore appear that proficient treatment of gastric or duodenal ulcer would require complete neutralization of free gastric acidity. This is best accomplished by food, alkalies and gastric aspirations. Temporary starvation and rectal feeding are unnecessary because three or five days' abstinence of food in the stomach is of little value in quieting spasm, peristalsis and tone, and the presence of non-neutralized acid in the fasting stomach may produce corrosive action, besides rhythmic systoles due to hunger interfere with physiologic gastric rest and irritate the ulcer.

The alkalies ordinarily used are sodium bicarbonate, calcium carbonate and heavy magnesium oxide, the magnesia being desirable to the point of bowel tolerance because of its high and continuing neutralizing power and its laxative properties, the sodium bicarbonate and calcium carbonate to complete the neutralization.

The alkalies are given frequently because of their fleeting action, with sufficient aspirations to make sure free acidity is controlled, therapeutic aspirations in case of pain with lavage if necessary, and routine aspirations to check control. It is desirable to use sufficient alkalies to neutralize the free acidity and not alkalinize the gastric contents. Combined acids do not interfere with ulcer healing, besides the normal habitat of gastric epithelium is an acid or at best a neutral medium. However, I have failed to see any pernicious effects from over alkalinization, more often are failures in treatment attributable to underneutralization. Indeed the best medical treatment for ulcer hemorrhage is overalkalinization and physiological gastric rest. Little if any stimulation of acid cells results from alkalies, and mucoid secretion is reduced by removing the acid irritation of the ulcer. Besides complete neutralization lessens the tone and motility of the stomach, removes pyloric inhibition, and enables the stomach to empty more readily, more easily and completely and with less irritation to the gastric or duodenal ulcer.

No doubt there is an added increment of motility from gastric aspiration or lavage, however the slight disturbance of relative gastric physiological rest is minor compared to the failure of underneutralization with its consequent increased gastric tone and motility and local irritative and corrosive action.

Food combines free acid forming acid albumins and peptones which interfere but little with ulcer healing. Combined acids are readily neutralized by the alkaline juices of the duodenum which removes pyloric inhibition and enables the stomach and duodenum to empty more rapidly with the least effort and irritation and with consequent less acid secretion and more relative physiological rest.

Liquid carbohydrate mixtures (barley water, rice gruel, cream-of-wheat gruel, etc.) probably require the least gastric and duodenal digestion, excite the least acid secretion and pass relatively rapidly through the stomach and duodenum; but they have no acid combining power, have but little food value, are not balanced in proteins, carbohydrates and fats to properly and sufficiently nourish ulcer patients who usually are anemic and poorly nourished.

In the early treatment equal parts of milk and cream give us the most ideal food from every standpoint, the protein clot being of minor significance. The milk and cream should be given frequently and in small quantities in order that they may least disturb physiological rest, excite

least acid secretion, best neutralize free acidity, and furnish adequate heat calories for the resting individual, being alternated with alkalies adequate to complete neutralization of any free acid. Later in the treatment other foods are added, bearing in mind the principles stated.

"The old and generally accepted belief that gastric juice corrosion is the most important influence that retards the healing of ulcer receives confirmation from the results that are obtained by all methods of treatment that have contributed to the healing of ulcer. In the light of all present knowledge, the development of granulation tissue leading to the healing and final cicatrization of ulcer is promoted by a given type of medical or surgical treatment directly proportionate to the influence exerted by that treatment on the duration and intensity of gastric juice corrosion."

When to the clinical picture of chronic ulcer is added the evidence of pyloric obstruction, furnished by repeated vomiting of retained food, the presence of food in the fasting stomach, the presence of sarcinæ and continuous secretion, the occurrence of peristaltic waves and the demonstration of barium residue, the essential problem of treatment becomes how to relieve the mechanical interference and how to prevent complications, and give the patient the best opportunity for health and life and after usefulness.

To conscientiously solve this problem requires the answer to several questions; viz., (1) What is the danger of cancer on ulcer? (2) Can we hope in these types of cases for relief and cure from medical and dietetic treatment? (3) What does surgery offer? (4) What is the percent of mortality from medical and surgical treatment?

1. Because as has been stated by Smithies and the Mayos that 60 percent of gastric cancers, demonstrated surgically and pathologically, have antecedent histories, which clinically cannot be differentiated from chronic gastric ulcer, is no indication, even if it be true, of antecedent ulcer, as ulcer histories are evident in so many other conditions, as demonstrated by Cheny, Einhorn, Boas, Rosenhein, Sippy and many others. Einhorn says: "If I should select only cases in which I could make a diagnosis of cancer based on ulcer, I would have a proportion of one in twenty or less." In addition postmortem pathologists have often confused these cases with those in which cancer becomes necrosed and forms an ulcer on its base, which is of frequent occurrence. If the cancer is found at the base of a so-called ulcer it is good evidence that it was cancer from the beginning; if found on the margin of an indurated ulcer the base and cicatricial tissue free from cancer evidence is cancer developed from ulcer. There is practically always more or less ulceration in cases of cancer, but that is an entirely different proposition from the development of cancer from ulcer.

Cancer histories ordinarily appear suddenly in an individual previously healthy, with few antecedent gastric symptoms. It is true we may have cancer with antecedent ulcer history, but ulcer symptoms do not always mean ulcer, and ulcer symptomatology is atypical and especially gastric ulcers. Even with these chances of error, ulcer history preceding gastric cancer is not the rule. It will not do to say that if careful histories were taken ulcer evidence would be found. This may be true in some instances, but the evidence of the best clinicians bears out the above statements.

Friedenwald in his clinical history of 1,000 cases of cancer of the stomach found only 23 percent that gave a history of any previous digestive troubles, and only 7.3 percent in which previous history could be interpreted to mean chronic gastric ulcer. Lockwood says that among 174 cases of gastric cancer he found only 7 percent that gave a history pointing to previous ulcer. Boas says such metamorphoses (ulcer to cancer) is not to be numbered among frequent occurrences.

No doubt cancer develops on ulcer, but the reports of the Mayos of such metamorphoses is far too high if we are to believe the experience of a large number of clinicians, pathologists and surgeons, and to operate all gastric ulcers on the ground that they are potential cancers would be applying to all cases a method of treatment applicable to the minority of cases, and the mortality from operation would be greater than the mortality of subsequent cancer, for these operations are not all performed by the Mayos or by those surgeons equally skilled.

2. Can we hope in these types of cases for relief and cure from medical and dietetic treatment?

That chronic gastric ulcers heal by granulation and fibrosis under proper conditions the same as chronic ulcers in other portions of the body cannot be denied. Will Mayo says: "While no one would contend that every gastric ulcer should be surgically treated, we at least should agree that if permanent cure does not take place within a reasonable period, other things being equal, the patient should have surgical treatment."

Experience has demonstrated that pyloric spasm and inflammatory exudation in pyloric and duodenal ulcer, producing mechanical obstruction, disappear under careful and energetic medical and dietetic treatment and rest. Round cells and other exudative products are removed, the infiltrated tissue grows thinner in all directions, the edema disappears and the pyloric

opening becomes more patent, when healing of the ulcer takes place, notwithstanding the tendency of fibrous tissue to contract.

No one claims that fibrous tissue once formed is ever removed but if the stomach after treatment is able to empty on time a motor meal without distress and with moderate motility, regardless of the tumefaction or deformity resulting from the fibrous healing of chronic ulcer, medical treatment has accomplished as much as most surgical measures usually offer, viz., mechanical relief.

If after reasonable time the mechanical obstruction is not amenable to careful and energetic medical and dietetic treatment and rest, or if relapses occur, or if the individual is approaching the cancer age and having continuous rather than intermittent type of gastric disturbance, exploratory and if necessary radical operation is indicated.

3. What can surgery offer?

I shall leave this question to the men qualified to answer. However, it seems to me that the only operation that offers cure of gastric and duodenal ulcer is excision or cauterization of the ulcer combined with posterior gastro-enterostomy.

After gastro-enterostomy alone food and secretions continue to pass through the pylorus proportionately to the size of the opening that exists through the strictured area of the pylorus and duodenum, and the reason the ulcer heals in the course of time after gastro-enterostomy is the same as the reason that a majority of the non-obstructive types of ulcers heal by various methods of treatment or by no treatment, viz., better drainage and less duration and intensity of gastric juice corrosion.

No one questions the indication for surgery in the complications of ulcer not amenable to medical and dietetic treatment. In my judgment surgery is a necessary part in the treatment of selective cases of gastric and duodenal ulcers, and the medical man must assume the responsibility, and it is just as much his duty to provide a competent surgeon as to provide a competent medical treatment.

4. What is the percent of mortality from medical and surgical treatment?

The operative mortality record from the Mayos of gastric ulcers is 4.5 percent, and of duodenal ulcers 2 percent. The mortuary record for the first six years following operations for gastric ulcer compared to the same number of persons from the general population with like distribution as to age and sex, is four times as great for the first year, three times as great for the second year, two and one-half times as great for the third year, twice as great for the fourth and fifth years, and equal for the sixth year. An average of 2¾ percent greater for the six years. No such difference was observed after operation for duodenal ulcer. No statistics are available in non-operated cases of gastric and duodenal ulcer, and accurate statistics in this group will probably never be entirely possible, because the uncertainties in diagnosis discount more or less the dependability of such figures.

The diagnosis and treatment of gastric and duodenal ulcer are among the most difficult things in medicine and surgery. The medical man, the surgeon, the laboratory man, the roentgenologist and the pathologist should work together. It is unjust to unnecessarily subject the patient to surgery or a long course of medical treatment when careful diagnosis would prevent. On the other hand it is just as wrong to deprive the patient of necessary surgical or medical care. A few questions and a prescription or exploratory incision lead to medical and surgical disrepute. Too often do we have patients following abdominal or pelvic operations with symptoms the same or exaggerated, or patients treated medically when the condition is obviously surgical. We probably differ as to what constitutes a medical or surgical condition, but it should be a difference of careful analysis and open mind and not one of arrogant opinion. With the most careful and conscientious work and the closest cooperation mistakes are made which after thought shows to be indefensible.

ULCER OF THE STOMACH AND DUODENUM

SURGICAL TREATMENT*

JOSEPH RILUS EASTMAN, M.D.
INDIANAPOLIS, INDIANA

A majority of cases of gastric ulcer which refuse to yield to medical treatment are curable by surgery. The oldest and perhaps most important indication for surgery is represented by cicatricial narrowing of the pylorus due to healed or healing ulcer. Here the correct treatment is not far to seek. It consists in the establishment of a new avenue of communication between the stomach and small intestine by means of gastroenterostomy and less frequently by operative widening of the narrowed pylorus—the pyloroplasty.

In early ulcer at or near the pylorus gastroenterostomy by diverting the stream of stomach contents protects the ulcerated area and favors cure. Patterson of London has contended that the mechanical or anatomic conception of gastroenterostomy is erroneous. He does not look upon it as a drainage or food short circuiting procedure, attaching little importance to this

*One of the papers of a symposium presented before the Indiana State Medical Association, Indianapolis Session, September, 1921.

phase, but regards it as a physiologic or chemical operation and maintains that the cure of gastric ulcer after gastroenterostomy is brought about by the entrance of alkaline duodenal juices into the stomach through the new stoma, the hyperacidity of the stomach contents being thus overcome and healing effected.

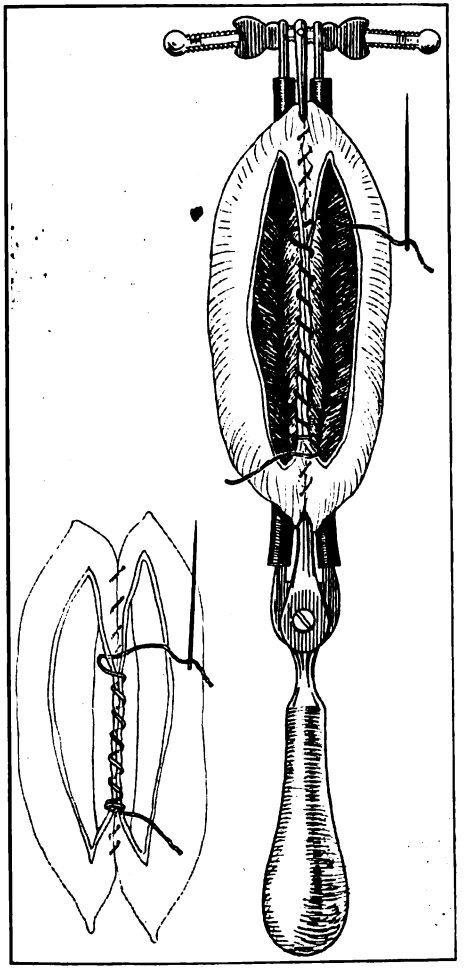

Fig. 1—First or lower half of hemostatic suture introduced as simple over-and-over stitch—may permit bleeding.

Cure of gastric ulcer following anterior gastroenterostomy which affects drainage only, imperfectly, and other data support the claims of Patterson. On the other hand, it is difficult to explain the cure of gastric ulcer after pyloric exclusion, for example by Von Eiselsberg's plan (in which the stomach is divided toward the cardia, the ends closed and gastroenterostomy done on the cardial stomach sack) by assuming a change in stomach chemistry, since here the new stoma establishes no new communication between the duodenum and pars pylorica.

It has been maintained by the friends of Patterson's view that cure of ulcer of the cardiac end by gastroenterostomy cannot be due to relief of irritation of the ulcer area through short circuiting, hence they turn to the changed chemistry or alkalinization by duodenal contents for explanation. However, it seems just as reasonable to regard gastroenterostomy in ulcer of the cardiac end as a step which cures by overcoming stagnation of stomach contents, reducing hyperacidity by more rapid emptying of the stomach and this need not imply disrespect for the view that entrance of bile and pancreatic

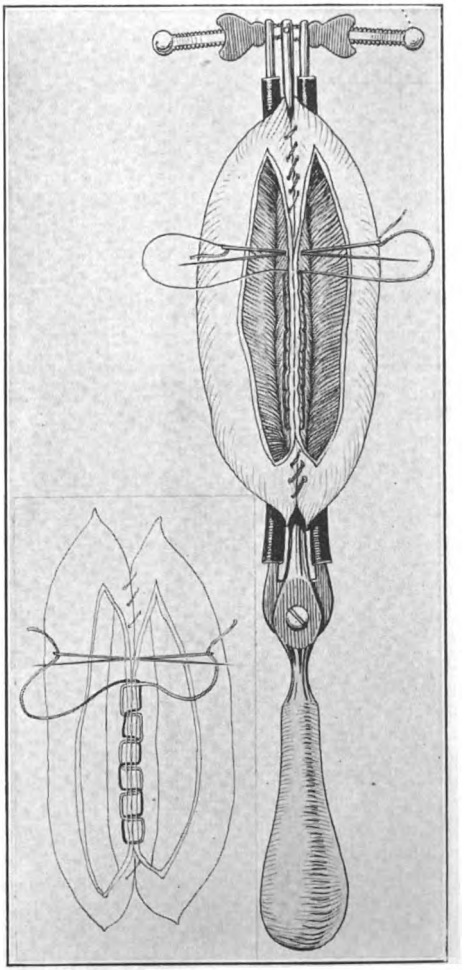

Fig. 2—Hemostatic suture uniting mucous membrane introduced as Cobbler's or Harness Maker's—waxed end is employed.

juice through the new stoma is an important factor in cure of ulcus ventriculi by gastroenterostomy. But regardless of the view which one may favor as to the way in which gastroenterostomy cures gastric ulcer, the fact remains unshaken—gastroenterostomy does cure benign ulcer and with gratifying regularity.

The operative mortality of gastroenterostomy depends upon many factors, but should be comparatively slight. It is certainly small in all those patients which have not been weakened by inanition and repeated hemorrhages. In cicatricial stenosis of the pylorus the good results of gastroenterostomy are prompt to appear and lasting. The motor and secretory activity of the stomach returns to normal, or approaches it. In ulcer of the pylorus gastroenterostomy added to pyloric exclusion as with the Wilm's facia ring nearly always brings cure.

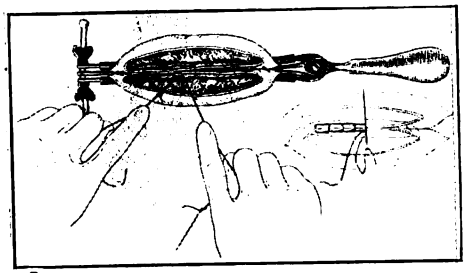

Fig. 3—Running knotted loop suture to control bleeding of mucous membrane. Introduced almost as readily as a simple continuous over-and-over stitch, but is in effect a series of interlocking interrupted sutures.

The ulcers of the body of the stomach, especially those of the lesser curvature, are not always relieved by gastroenterostomy. Bamberger found that eighty percent of all gastric ulcers are cured by gastroenterostomy. Sixty percent of ulcers of the body of the stomach are thus relieved. It should be remembered that it is the ulcer distant from the pylorus which is most likely to be associated with inflammatory tumors of the stomach wall, the callous penetrating form not infrequently involving the pancreas, liver and spleen. These are the cases requiring cauterization or resection in addition to posterior gastroenterostomy. (Rodman operation or the Bilroth number one or number two.) The importance of resection of the ulcer bearing area in such cases is only too often emphasized by the post-operative finding of carcinoma in clinically benign callous ulcer.

Crile (*Ohio State Medical Journal*, Sept. 1, 1921) is convinced that no absolute differential diagnosis between cancer and ulcer is possible before operation; nor at the operation except by the pathologist; nor by the pathologist in certain borderline cases. Irrespective of operative treatment, the dietetic management of all ulcer cases is an essential before and after surgical intervention. In patients, exhausted by long standing ulcer or cancer, conservation and restoration of bodily economy must be secured by restoration and preservation of the acid-alkali balance of the cells, particularly of the brain and liver; maintenance of an adequate circulation; as well as a minimizing and, where indicated, a dividing of the trauma of operation.

There is, of course, no debate as to the value of surgery in perforation of stomach ulcer. This happens most frequently in ulcers near the pylorus and here, owing to the mobility of this portion, the chances of adhesion formation with walling off are slight. Pain, nausea, collapse, the boardy, hard, concave, canoe abdomen mean immediate operation, closure of the perforation with or without gastroenterostomy, according to the condition of the patient. A patch of omentum over the sutures closing the perforation is often of value, and careful mopping out of the escaped contents without irrigation is imperative. We are advised by some surgeons to close the abdominal wound after such an operation without drainage. I cannot bring myself to this view.

In perforating duodenal ulcer, the chances of cure by operation are not so good as in gastric ulcer, but in either case the result is nearly always determined by the ability of the attending physician to diagnosticate the condition promptly. In the first twenty-four hours the chances of success sink from eighty to thirty percent. In duodenal ulcer, before perforation most surgeons incline to posterior gastroenterostomy with pyloroplication, pylorus closure by facia, or pyloric exclusion.

The most rational method of gastroenterostomy is the so-called short loop posterior type, the gastroenterostomia retrocolica of von Hacker, with the added precaution of Peterson and Mayo, in which the stoma is made in the very uppermost part of the jejunum, which lies against the posterior stomach wall, separated only by the weblike transverse mesocolon. If this precaution is observed, vicious circle is practically eliminated. The opening in the intestine should be at the flexura duodenojejunalis, or at a more deeply situated point. The transverse colon is delivered through the wound, the mesocolon spread out, and a nonvascular area found. The clamp is laid on the gut and stomach and the seroserous anular proximating suture of No. chromic catgut is passed close to the clamp

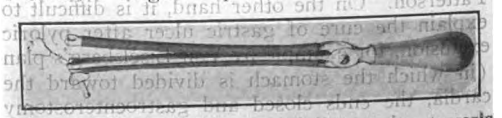

Fig. 4—An efficient and [illegible] clamp of uncomplicated construc[illegible]

jaws in a line a few millimeters below the lines of incision into the gut and stomach. Obviously, the seroserous suture must extend beyond the lines of incision in the gut and stomach at both ends. Before continuing the serous suture around and above the incisions, the margins of the openings in the gut and stomach are united

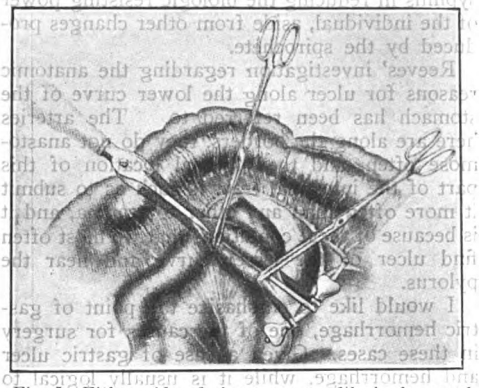

Fig. 5—Either side of clamp can readily be loosened for readjusting stomach or intestine by unscrewing the wing-nut.

by the hemostatic suture of catgut. This suture may be introduced for the first half of its length in the simple over and over fashion, or as a cobbler's or a harness maker's stitch with a needle at each end, this insuring better hemostasis in a position which after completion of the operation would be difficult of access. For this hemostatic suture the writer uses the running knotted loop suture shown in illustration number three. This knotted suture prevents bleeding of the mucous membrane in a most satisfactory degree. It is introduced as readily as a simple running or continuous suture and has the effect of a row of interlocking interrupted sutures. If a hemostatic suture is begun as a simple over and over stitch, it is continued over the stoma as a running Cushing suture, applied by the outside-inside, inside-outside rule. Either the cobbler stitch or the knotted loop suture can be carried completely around the stoma, inverting and securing the margins as well or even better than the running Cushing suture. After the hemostatic suture is in place all around, the serosa suture is picked up and applied in the last half of its course. In posterior gastroenterostomy additional guy sutures are not often necessary. A step of great importance is the securing of the margin of the openings in the transverse mesocolon to the stomach by interrupted sutures to prevent prolapse and hernia of the stomach through this layer.

The gastroenterostomy clamp shown in the illustrations has, it is believed, advantages of construction and application sufficient to justify its recommendation to anyone doing operations on the stomach and intestines.

In applying this clamp there need be no confusion as to which is the top or bottom of the instrument, nor as to which is the right or left side. Pressure can be gauged accurately by turning the wing-nut which rests with a ball-seat in a concavity on the outer side of the end of each of the lateral bars. The wing-nut moves upon a short, thin, threaded lever which is attached by a hinge joint to the end of the median bar. The lever swings radially into a slot at the distal end of the lateral bars or jaws of the clamp. It is quite easy to release pressure on either side without loosening the other side so that, for example, the intestine or stomach may be drawn up farther into the grasp of the clamp, if desired, on either side, without releasing the opposite side. This can be done with other intestinal anastomosis clamps; but as in the case of scissors-handled forceps, this step may require a little time and art.

After the introduction of the inner hemostatic suture both sides may be released, so that the seroserous approximation secured by the outer suture may be accomplished without traction and consequent tearing out of the suture and without danger of the operative field slipping into the abdomen and out of convenient reach. The lever and wing-nut device at the distal end of the clamp has been used in other clamps and its value is well known to those who are familiar with the embarrassments incident to imperfect

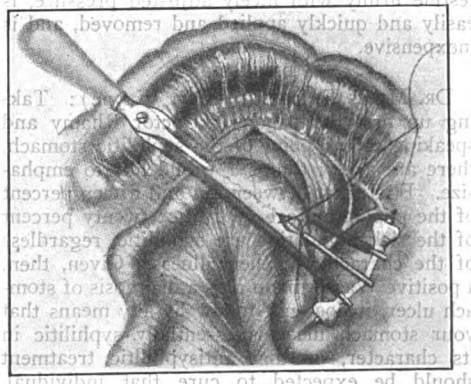

Fig. 6—Both sides of the clamp can be loosened to permit completion, the operative field still being held up in favorable position.

closure at the distal end of the anastomosis forceps. After the completion of the anastomosis, the threaded levers are placed in alignment with the median bar before withdrawal of the instrument. The slanting margins of the heart-shaped wing-nuts, and their small size, prevent catching of the instrument as it is withdrawn.

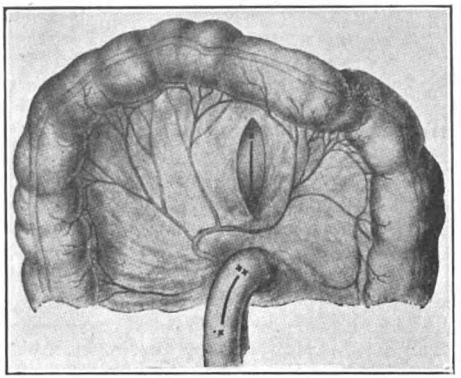

Fig. 7—Position of incisions in jejunum and stomach in posterior no loop gastro-enterostomy. Intestinal incision at duodeno-jejunal flexure.

The median bar of the clamp is not so thick as it is in other clamps, thus minimizing the possibility of tension upon any other sutures. The large proximal hinged joint of the instrument has been made very heavy and strong intentionally with a view to securing durability and firmness.

In order to secure an elastic spring pressure along the full length of the clamp, the bars deviate gradually from the median bar in the distal half and are so tempered that the screwing down of the wing-nuts accomplishes firm pressure without crushing.

This instrument is light in weight, simple and convenient to use, holds the stomach or intestine firmly with nicely adjusted pressure, is easily and quickly applied and removed, and is inexpensive.

DISCUSSION

DR. MILES F. PORTER (Fort Wayne): Taking up first the paper of Doctor Rhamy and speaking to the point of the syphilitic stomach, there are a few things I would like to emphasize. First, that between ten and fifteen percent of the population are syphilitic; twenty percent of the sick population are syphilitic, regardless of the character of their illness. Given, then, a positive Wassermann plus a diagnosis of stomach ulcer, it does not follow by any means that your stomach ulcer is essentially syphilitic in its character, or that antisyphilitic treatment should be expected to cure that individual. Given a case of stomach ulcer in a syphilitic it may be that that ulcer is in a measure the direct result of the syphilitic infection, and, on the other hand, it may be that the syphilitic infection is an etiologic factor, but only in an indirect way. That is to say, that the ulcer in this particular case is not due to involvement of the connective tissue by virtue of the stimulation from the spirochete, but due to the general fact that syphilis reduces the resistance of the individual. Some of you will recall that a large percentage of all of our cases of meningitis and hip joint disease does occur in syphilitic trouble. In Melbourne, Australia, out of the ten percent of the child population which is syphilitic the Children's Hospital gets over fifty percent of its sick babies. This is the effect of syphilis in reducing the biologic resisting power of the individual, aside from other changes produced by the spirochete.

Reeves' investigation regarding the anatomic reasons for ulcer along the lower curve of the stomach has been referred to. The arteries here are along the borders, they do not anastomose often, and the physical location of this part of the intestinal tract is such as to submit it more often than any other to trauma, and it is because of these conditions that we most often find ulcer of the lesser curve and near the pylorus.

I would like to emphasize the point of gastric hemorrhage, one of the causes for surgery in these cases. Given a case of gastric ulcer and hemorrhage, while it is usually logical to assume that the hemorrhage is from the ulcer, yet that is not always true. I have had the misfortune, or the fortune if you please, to operate for duodenal ulcer and have my patient continue to bleed; then to refer him to another clinic and have the pyloric section of the stomach removed. He had a duodenal ulcer and hemorrhage from the ulcer; but he also had hemorrhage from arterial degeneration consequent upon myocardial renal disease and high pressure, and the bleeding happened to come from the stomach.

I have for some years used, with great satisfaction, the clamp shown by Doctor Eastman.

I want to call attention to a possible misapprehension that may come from quotation of the statistics from the Mayo Clinic as to deaths following treatment. I want to say that all of the deaths in the Mayo Clinic are regarded as deaths from operation, provided the individual dies in the hospital while there, perhaps in ten days or two weeks' time.

I would also like to say in regard to the number of cases cured medically or surgically, that the ulcer of the stomach that comes to the surgeon has been cured by the internal man on an average of six times before it is finally and permanently cured by the surgeon.

DR. A. B. GRAHAM (Indianapolis): That we are not of one and the same opinion, and that as yet we have failed, as McCaskey says, to evolve a "harmony" out of the conflicting current views on so-called peptic ulcer, is substantiated clearly when we review carefully the abstracts of the papers comprising the exceedingly interesting symposium which has been presented for our consideration this morning.

As to the etiology and pathology of gastric and duodenal ulcer, Doctor Rhamy has covered this field in a most thorough manner. Until more accurate data or proof is furnished we shall continue to agree with him in the opinion that as to the etiology of ulcer the essential factor is a localized loss of vitality permitting auto-digestion.

Many gastric and duodenal ulcers are easy of diagnosis; some demand all the methods of examination at our command for the making of diagnosis; and in a small percentage of cases we fail to make a correct diagnosis. I agree with Dr. Foreman that gastric secretion is influenced by many factors outside of the stomach, and should receive due consideration in every case; but my personal experience will not enable me to corroborate his statement that the amount and character of the gastric secretion gives little knowledge of the pathology of the stomach. I appreciate fully that in this opinion he has the support of some well-known physicians, and yet, after twenty-five years' experience in gastro-enterologic work, both medical and surgical, it is my opinion that gastric secretions give important data which is valuable in the making of a diagnosis of gastric and duodenal ulcer. Gastric analysis alone will not make the diagnosis of ulcer, but I do maintain that in my experience it has proven of sufficient importance to maintain a prominent position with the other methods of examination employed daily in our work. Without a gastric anaylsis it is impossible to say with any degree of certainty what is the secretory or motor activity of a given stomach, but the routine examination of the gastric contents, properly interpreted, gives us a fairly accurate determination of the secretory and motor activity, it enables us to study and interpret the chyme, the presence or absence of mucous or any abnormal material, and, finally, we can determine the presence or absence of macroscopic or occult blood—all of which assists in the correct diagnosis of ulcer. In former years, when we employed the Ewald tube and expressed the stomach contents one hour after the ingestion of the test breakfast, our studies of these contents did not give us as valuable data as we are obtaining at the present time. It was with this method (the horror of the large tube) that factors outside of the stomach, mostly psychic, influenced the secretory activity to such an extent as to spell failure in a small percentage of our cases and prove of little value as a diagnostic method. During the past three years we have been making fractional studies of the gastric contents, employing for this work the gastro-duodenal tube. In a certain percentage of cases the psychic element is also present, but since we keep the tube *in situ* from an hour to an hour and a half, the patient loses her fear of the tube and we secure very definite data as to the secretory activity, where a correct technique is followed. With this method our percentage of correct diagnoses has shown a decided upward trend, as has been corroborated by both the roentgenologists and surgeons who have been associated with us in this work.

My statistics do not conform with those of Moynihan and others—that 20 percent of ulcer cases show a hyperacidity, and that the other 80 percent are equally divided between normal and diminished secretory activity. With the fractional method of study, 80 percent of our patients have shown a secretory activity in excess of the highest point of normal.

I am unable to support the statement that gastric symptoms are motor rather than secretory. My records show that in those cases in which the secretory activity has been highest, the misery and pain has been the more intense, and the spasticity as revealed by the fluoroscope the more pronounced. Motor activity, tension and spasticity do play a role in the production of this misery or pain, but when one repeatedly relieves this symptom by the administration of alkaline medication, it is difficult to eliminate the direct contact of HCl with the ulcer as the real primary factor of the pain and spasticity in many cases. The same is true of antispasmodics, such as belladonna and atropin.

As to the statement that the relief of pain is not a safe guide in treatment, I can only say that in my own work I have always felt somewhat secure when my patients inform me that they are free from pain.

As to the treatment, the most important matter from a prophylactic standpoint is the subject of excess secretion, and matters pertaining to the general state of health, such as nervous symptoms, anemia, debility and sub-nutrition, should be cared for. Every effort should be made to decrease the stomach secretion and increase the general state of health.

When the diagnosis has been made the patient should be put to bed and the strictest discipline insisted upon in the way of complete rest, diet, medicine and hygiene. Failures in medical treatment come from indifferent or incomplete discipline, and by its observance such complications as hemorrhage and perforations are minimized. At least three weeks (preferably five) in bed should be insisted upon, and appropriate treatment should then be instituted for several months, even though the patient be symptom-free of ulcer. Even under the best of conditions and in the best hands failure results, and this is especially true in perforation, post-ulcer sequelæ, and chronic ulcer. I believe that uncomplicated ulcer, in its early stages and when properly cared for, is always a medical condition.

It cannot be denied that surgical intervention, with its improved technique, and with more careful selection of cases, is showing a marked diminution in mortality and increased success each year. Surgical interference in hemorrhage of the copious type is contraindicated. In perforation, always a surgical condition, medical treatment can show 5 percent recoveries, while early surgery shows 65 percent recoveries.

Post-ulcer conditions, such as hour-glass contraction, pyloric stenosis, peri-gastric adhesions, persistent gastrosucorrhea, are all surgical conditions. My experience has been that a majority of true chronic ulcers are surgical conditions. Some such cases can be relieved, or even cured by medical therapy, but the percentage is exceedingly small.

I have never seen or heard of the comparison of gastric ulcer with anal fissure. Those of us who are called upon to treat the latter condition know that when it is superficial a well-directed local treatment as a rule effects a cure; but when it has become a chronic ulcer involving the external sphincter muscle and surrounded by cicatricial tissue, surgery is our only hope of effecting a cure.

In conclusion, I hold to the opinion that gastric and duodenal surgery should be performed by men well qualified for such work. This is no work for the novice, but calls forth the best work of which the best surgeon is capable.

DR. W. D. ASBURY (Terre Haute): This symposium presupposes two lines of treatment for gastric and duodenal ulcer—medical and surgical—and our earnest effort should be, not our individual thought about the matter, but the thing that will bring the most good to our patients, whether that be medical or surgical treatment.

The term "peptic ulcer" is not a good one and should be discarded. It is misleading.

As to the cause of gastric and duodenal ulcer, perhaps no one has solved that problem. The experimentally produced gastric ulcers, such as those produced by Carlson, are not at all comparable with the ulcers one finds in his patients, nor is the healing of these ulcers to be compared with the healing process in actual practice. The predisposition of the patient, the lowered resistance, and many other factors make an artificially produced gastric ulcer very different in its formation and healing from those ulcers in patients who come to us for treatment. Hyperacidity, whether the result or the cause, has something to do with gastric ulcer in most cases, and good results have been accomplished when this acidity is scientifically controlled both day and night.

Every patient coming for examination for gastric and duodenal ulcer should have a blood Wassermann, and pulmonary tuberculosis with stomach symptoms should be carefully excluded. In making a diagnosis no one symptom or test is sufficient. A comprehensive and accurate history is of prime importance. A fluoroscopic examination is often of greater diagnostic value than an x-ray on account of motility and mobility.

DR. F. W. FOXWORTHY (Indianapolis): One of the essayists has, of his own volition, designated two periods in the life history of gastric ulcer. The first is the period before the ulcer exists, which he kindly assigns to the internist; the second, or the one of actual existence from beginning to end, he has the delusion belongs to the surgeon only. May I not add a third period, which often occurs after operation and only too often is sent to the internist for relief—the period of recurrence of previous symptoms. The great life insurance companies find that applicants who have had a gastro-enterostomy have a higher mortality than when the ulcer is treated by medication; Smithies, reporting 273 cases of gastro-enterostomy for ulcer, shows only 20.9 percent free from clinical symptoms afterwards.

Judd reports 101 cases of jejunal ulcer following gastro-enterostomy, 25 percent of which showed foreign material (threads).

Asche, four years after a gastro-enterostomy, found a double thread two inches long, causing the ulcer.

Mandl shows fully 200 cases of post-operative peptic ulcers. He states that scraps of silk suture have been found so often in the vicinity of peptic ulcer that there can be no doubt this is a contributing factor in some cases.

Haberer, with 205 cases of operated duodenal ulcer, states that gastro-enterostomy does not give very satisfactory results. He has several times been obliged to operate for recurrence when the pylorus has been cut off.

Payr, reporting 59 cases of duodenal ulcer operated, is pessimistic as to the outcome, referring to the comparative frequency of peptic ulcer after radical intervention.

Davis reports from 15 to 40 percent of operations performed for gastric ulcers as failures; at least, they do not restore the patient to sound health.

Eusterman, reporting 82 cases of post-operative ulcer from the Mayo Clinic, states 47 followed gastro-enterostomy elsewhere.

Eggleston reports only 42 percent of cured ulcers from gastro-enterostomy.

Moynihan believes the most rational of all methods of treatment is that introduced by Sippy, which appears to meet those conditions in the stomach which must be controlled before an ulcer can have a chance to heal. He further states that a really serious attempt to treat all

cases of gastric ulcer by medical treatment should be made.

I quote from Dr. George Crile, in a personal letter to me dated September 24, 1921:

"Medical treatment should be given a thorough trial at first, excepting in the following cases, when surgical intervention should not be delayed:

"1. Obstruction of the pylorus.

"2. Marked perigastric adhesions interfering with the emptying of the stomach.

"3. When medical treatment has been given a thorough trial without any relief of symptoms.

"4. In case of perforation.

"5. In the presence of persistent hemorrhage.

"6. When there is any question regarding the presence of carcinoma, either primary or developed in the site of an old ulcer."

I also asked a distinguished surgeon if, with all the knowledge he had of gastric ulcer and its treatment, he would allow himself to be operated on here for gastric ulcer. He replied, "Not at all. There are only three surgeons in the United States who could operate on me." I then asked him if he would submit to treatment by an internist, using the best medical treatment available, and his reply was in the affirmative. Is not this evidence conclusive?

Surgery has reached its highest point, according to many observers. Internal medicine is just starting, and within the next few years even greater advances may be expected. The Mayo Clinic recognizes this in their installation of 400 beds for internal medical treatment. Our hope is that Indiana surgeons may not be laggard, as the wheels of Progress are continually moving onward.

DR. GEORGE W. MCCASKEY (Fort Wayne): In regard to the etiology of gastric ulcer, there are a number of factors, chemical, vascular and others, which affect the continuity of the gastric and duodenal mucosa. I think it has been fully established that traumatism and chemical factors cannot produce a typical clinical ulcer, such as we have to deal with in our patients, and if that be true, what is the ultimate, final cause of the ulcer? My belief is that Rosenow's view of the elective affinity of certain bacteria for the stomach, kidneys and other organs furnishes the most plausible explanation of gastric ulcer. I also believe that the infection is always hematogenous in its approach to the stomach, and that were it not for this hematogenous infection of the stomach we probably would never have a typical clinical ulcer. That may be dogmatic, and of course we must wait for further information and evidence before we can positively decide this question; but that is my personal belief.

The treatment I think should first be medical, and for a long enough time to prove that medical treatment is inefficient. I think it should not be surgical until it has been proven that relief from medical treatment cannot be obtained.

I would like to protest against the too routine performance of gastro-jejunostomy. First, because of the perverted anatomy and physiology which it leaves; second, because of the not infrequent occurrence of jejunal ulcer; third, because in a large number of cases in which jejunal ulcer does not occur, there is persistent jejunal irritation, or possibly erosions which leave the patient symptomatically unimproved; fourth, because it fails to cure many cases, and fifth, because the operative hazard to life, while very small with highly skilful surgeons, increases greatly in the hands of less skilful operators, and cannot be ignored.

In general, it may be said that the results of medical treatment in a very large proportion of cases is quite as good as the surgical, unless extensive induration or threatened malignancy obtains, neither of which is cured by gastro-jejunostomy.

The recurrence of ulcer after medical treatment will become less and less frequent when both the internist and patient do their duty. The former includes the removal of etiologic factors and the careful education of the patient as to his future regime over a period of years. The latter, a strict compliance on the part of the patient with instructions given, with the distinct understanding that the ultimate results depend quite as much upon him as upon the physician.

DR. H. O. PANTZER (Indianapolis): Speaking of the etiology, one factor has not been mentioned which to me seems of great importance. I refer to anatomical irregularities of the stomach and its neighboring organs. They do prevail to a surprising extent. And they do give rise to functional disturbances which go with physical insult, chemical irritation, and infection.

I have for thirty years observed this line of thought incidentally to my surgical work. My first case was reported in 1891, and since that time I have frequently published my further observations and conclusions. I am convinced that anatomical irregularities are the predisposing and primary cause, not only of gastric ulcer, but of all abdominal diseases in a large percent of cases. I have also convinced myself that many of the ills of infant life—now too freely ascribed to impaired mother's milk, and errors in diet—in reality are owing to congenital anatomical irregularities of form and position, and the subsequent disturbances of function.

At first Nature, so to speak, "balks", then creates a temporary tolerance of them, which processes repeat themselves. Later these conditions are recognized as formidable pathological entities, of which gastric ulcer is but a sample. With light touch (as practiced by the blind), with x-ray, and with intensive study of the symptomatology and its causes, we will—I may hope—learn to recognize these conditions in the infant, and then shall operate these conditions early and thus avert long suffering ending in final critical disease, as which alone we now treat them.

DR. W. H. FOREMAN (closing): In regard to the acidity of the stomach, I made the statement that the amount of acidity was of little value in diagnosis because so many other conditions can produce hyperacidity; but that after ulcer has been diagnosed, then the amount of acid in the stomach assumes great importance in the treatment.

The discussion this morning has evidenced the general opinion of the medical profession of the state of Indiana. Two or three years ago if we had discussed a symposium like this the surgeons would have jumped all over us and said that ulcer belongs to the surgeon exclusively. Now the general opinion among the profession is that ulcer belongs to the internist for diagnosis and for early treatment at least, and if it does not respond to treatment, then surgical assistance is necessary. Even after surgery the patient must have as careful medical and dietary treatment as if no surgery had been performed.

What Doctor Porter says may be true. I said in my paper that not all cases are cured, either medically or surgically. I have had cases where the surgeon has operated and the patients have had a recurrence.

DR. J. R. EASTMAN (closing): With relation to Doctor Foreman's statement that two or three years ago the surgeons would have said that every stomach ulcer is a surgical condition, I do not agree with him. Surgeons were hardly so radical as that.

I think Doctor Foxworthy is unduly alarmed at the aggressiveness of the surgeons in this particular field. I do not think the surgeons demand that they be permitted to operate in every case of gastric ulcer. As a rule we do not see these cases until there are perigastric adhesions, hemorrhage and stenosis, and then they are indeed surgical cases. There is a time for medical treatment of gastric or duodenal ulcer, and there is also a time for surgical interference. We must remember the relation of carcinoma of the stomach to ulcer. Every ulcer may become a cancer, and as was said by Dr. William Mayo, every cancer of the stomach was probably at one time an ulcer.

THE PHYSICIAN

"THE REJUVENATION OF MEDICAL ETHICS"*

FRANK B. WYNN
INDIANAPOLIS

Perhaps there is no phase of medicine concerning which there is so much misinformation as concerning the commonly designated "Code of Medical Ethics". Almost without exception, intelligent people know of the existence of a pact amongst decent practitioners, but the knowledge is vague. Some entertain the view that it is a sort of oath; others that it is a traditional custom descended from the ancient fathers in medicine; quite general is the opinion that it is an unwritten law of the profession containing obsolete rules of conduct, neither justified in wisdom nor right, but which long usage makes it impossible to shake off. In the lay press the view is often expressed by inuendo if not by direct words, that "Medical Ethics" is a species of folly characterized by narrowness, not at all in keeping with the spirit of modern progress. By those outside the pale of organized medical forces, this idea is held aloft and painted with ridicule. Should there not be some concerted and forceful effort made to correct these erroneous ideas entertained in the public mind?

How remote these conceptions are from the truth, all know who are familiar with the Principles of Medical Ethics. It represents a most commendable effort on the part of the intelligent and progressive elements of medicine, to conserve the idealism of the medical past. It seeks to elevate the standards of practice and scientific attainment, of gentlemanly and moral conduct, for the benefit of the patient first of all; for the mutual instruction and elevation of the profession; and in the interest of the public weal. Should we ever fall from these high standards, we will no longer be worthy the designation of a profession, but must march in the ranks of tradesmen.

Searching for the causes of public mistrust of the "Code" they are found to exist in ignorance concerning its nature and purposes. Laymen are excusable for these erroneous conceptions and misapprehensions. I never yet have talked to one who had read the Principles of Medical Ethics. His knowledge of it came through hearsay or isolated acts of physicians which he could not understand, and not comprehending the rational and moral grounds for such action, he was likely to consider it queer and senseless. And so very naturally, one might say quite justly, our "Code" has come in for gibes and sneers. Physicians themselves not rarely also show their ignorance of the scope

*Seventeenth of a series of articles by Dr. Wynn which will appear regularly in THE JOURNAL.

and purpose of this instrument by falling in with the public judgment and condemning it by faint praise. In truth can the profession as a whole claim that any moving faith animates the rank and file in support of this "Charter of Achievement, Responsibility and Conduct"?

Had not progressive men from time to time in the history of organized medical development, made conscientious effort to formulate "By-laws" or "Principles" as a guide to professional conduct, they would have been most recreant to duty in their day and generation. As well think of the American Commonwealth without a Constitution, a religion without a creed, or the Bible without its Ten Commandments. Our "Code" is not a perfect instrument —never can be. With evolution in medical progress it will need revision to meet the changes which wisdom and experience have proved out, and found not wanting. For the present it will be to our mutual advantage to know better our commandments of "Shalts" and "Shalt-nots".

It is surprising and rather disheartening how few medical men are familiar with the Principles of Medical Ethics. This explains why they do not more frequently come to the defense of its teaching. This is owing in part I believe to the fact of its stilted form. That it is framed by Chapters, Articles and Sections is in conformity with usage in the writing of Constitutions and By-laws. This method has its practical value in enabling one to find quickly certain articles of the instrument. But it is open to the very serious objection that it lacks in readable qualities which hold one's interest and attention. Constitutions are very important in setting forth the aims and rules of action in organizations, but who takes any particular delight in reading them? They possess a sort of stereotyped monotony of mechanism which is repellant to enthusiasm. However fine and fundamental may be the American Constitution, does one gather enthusiasm from perusing its contents, as he does from reading the Declaration of Independence? The former is cold, concise to the point of mathematical exactness, so carefully wrought that not a word can be spared. It is the bulwark of wisdom and farsight, coming out of the fertile brain of Hamilton, protecting the liberties gained at so great a price, against future calamity. It is utterly devoid, however, of appeal to the imagination or emotions. In contrast to Hamilton's master work, contemplate the immortal instrument penned by Jefferson. It burns with righteous indignation, kindles the flame of patriotic fervor and lights the torch of liberty. Who is not proud of both? One served to arouse the builders of a republic to action and having served the purpose of the day, lives now chiefly as a beautiful historic sentiment. The other became the permanent foundation upon which the governmental structure of liberty rests.

In our present state of national unrest, following the world-war, millions of unassimilated foreigners upon our shores fail to comprehend the significance of American institutions. The American Constitution, however wise and just, is a cold and meaningless thing to them. Is not the imperative duty of the hour to read into the Constitution the spirit and the fire of the Declaration of Independence in order that they may know the price paid for liberty? When we who have enjoyed these blessings are aroused by a zeal like Paul of old, to proclaim again and again upon every hand, the sacrifices and the spirit out of which and through which our country has grown, there will come to these peoples conviction and conversion. As soon as they are nationally born again they will become fit subjects to live and work under a wise governing Constitution.

By analogy may it not be said of our constitution, "The Code of Medical Ethics," that like the American Constitution, it too needs to have read into it an awakening spirit of medical evangelism—which will renew the faith and arouse to more determined influence and power in medicine. For may it not be true that we have been carried from safe moorings by the world-wide wave of materialism? The captains of industry have occupied the stage of chief interest in our day and generation. Likewise the captains of medicine have marched to material conquest in laboratories, revealing cold facts; along the avenues of specialism, searching for isolated and unemotional truths—all splendid and serviceful achievements taking little account, however, of man as a thinking, feeling organism. In the light of these facts is it not well that we should come to our medical senses, giving proper evaluation to the ethical and moral phases of medicine.

It must be granted that the Principles of Medical Ethics is a remarkable instrument comprehending the very essence of wisdom which should govern the conduct and widen the vision of every right-thinking physician. But a deplorable weakness lies in its cold, stereotyped, constitution-like manner of presentation, which repels rather than invites contemplation. Certainly it has failed to bring conviction to the public mind, which views it with ill-concealed contempt. Nay, even more. There often arises wide-spread suspicion of concerted endeavors of physicians for the common weal. Is it an impending epidemic of small-pox in which general vaccination is urged, the cynical voice of suspicion is raised, charging the medical profession with planning a vaccination harvest. Should unsanitary conditions threaten the health

of the community and a courageous group of physicians take a firm stand for their correction, they may expect slanderous criticism of their motives. And among the opposition will sometimes be found the reactionary physician, who has become myopic to the broader view of Medical Ethics.

But of all the scoffers at the tenets of our medical creed, none equals in numbers or virulence of accusation the quasi-medical sects—the "rubbers" and "healers". When concerted effort is made by the profession to require of these mushroom practitioners the same fundamental literary and scientific training which accredited physicians must take, they protest furiously, crying persecution and monopoly. Thus have these anti-medical agitators and pseudo-practitioners shouted themselves into a position of prominence in the public mind. So securely established are they that legislatures pay homage in negative conduct regarding reforms, and because of their substantial contributions to the advertising columns of the lay press, the latter gives them a fattening publicity. Stoically we have suppressed our emotions and borne their brazen aggressiveness. The professional brain is dizzy with apprehensive anxiety of what may come to pass.

But let not the intensity of our zeal to punish or restrict the "irregulars" blind us to the existence of our own professional delinquencies. However venal and offensive their acts, has our conduct been above the suspicion of mercenary ambitions? Note the large number of general practitioners entering special fields, frankly confessing the motive is greater ease and larger income. Even the tendency of the time to group practice finds its most frequent argument a desire to augment incomes rather than cooperative study, and productive scientific effort. This statement is borne out by the fact of frequent failures of group efforts, from wreckage upon the rocks of financial controversy. If one would be still further convinced, listen to the casual conversation of a group of medical men in the physicians' waiting room of a general hospital. The theme of discussion is not so likely to be a recent article of great scientific interest, or the superior investigative work of some struggling young practitioner, but gossip about the volume of work or incomes of supposedly successful specialists.

Too generally the profession has become obsessed with the idea of magnitude, in practice rather than quality of work, or contributions to professional betterment. "Big Business" in medicine, like in the commercial and industrial world, may produce a few medical plutocrats, but its tendency will be to lower the general professional tone, and establish false standards of practice. It is not in keeping with the ancient traditions of medicine, nor consonant with "The Principles of Medical Ethics" that we should bow down before the Mammon of avarice.

Finally, may it not be contended that sufficient argument has been offered to justify the conclusion that there is urgent need, in these times of medical unrest, for a rejuvenation of "The Principles of Medical Ethics"? Let this instrument be considered not merely an epitome of the laws governing the moral conduct of physicians but a living, moving force to promote the ideals of medical progress. As the Decalogue was to the ancient Hebrews, so let the profession of medicine find light and guidance in a revival of *"The Ten Commandments of Medical Ethics"*.

THE TEN COMMANDMENTS OF MEDICAL ETHICS

I. *Reverence and Responsibility.*
Remember thy Creator in the days of professional youth. Bow reverently before the wonderful human body, sick or well, as thou wouldst before a sacred shrine, conscious of thy high duty; resolved to serve to the best of thy power, whether the patient be black or white, prince or pauper, saint or degenerate.

II. *Historic Appreciation.*
Honor thy father and thy mother. Likewise give praise to the fathers in medicine whose rich heritage of scientific and clinical truth has been handed down to thee through centuries of patient toil. Hold fast to that which is good, but let not prejudice coming out of the past blind thy vision to the newer truths of medical advancement.

III. *Keeping the Faith.*
Thou shalt not worship the graven images of false practice—of avarice and selfishness which eat at the very heart of medical idealism; of clever artifice or brazen quackery which knowingly deceives; of erratic isms and cults which tell but half truths, leading the ignorant and unwary astray.

IV. *Inviolable Confidences.*
Thou shalt not disclose the secrets confided to thy keeping by trusting patients unless they be of criminal or treasonable import. Nor shalt thou abuse the professional intimacy granted to thee by women, which becomes a professional and moral obligation thou shouldst hold inviolate.

V. *The Sanctity of Life.*
Thou shalt not hazard life unwarrantably; neither shalt thou shrink before the obvious perils of duty when life is at stake. The unborn shalt thou not destroy except after due consultation, it is deemed advisable for the larger saving of life. Suffer not death to

come through neglect in care of the sick, nor from failure in reading, study and counsel to gain the greatest benefit for the patient.

VI. *Professional Cooperation.*

Thou shalt not bear false witness against a worthy professional brother, but seek ever to protect his good name from calumnious attack by misinterpreting laymen. Of thy knowledge give him unstintingly, counselling and cooperating for medical progress.

VII. *Gentlemanly Conduct.*

Thou shalt not prate of cases nor countenance unseemly boasting of thy achievements in the lay press. Always a gentleman, let thy conduct be reserved but without cowardice; courteous but free from flattery; dignified but of warm heart; tender in ministration but firm in command; clean of body, speech and mind.

VIII. *Honesty in Business.*

Thou shalt not steal; neither shalt thou make extortionate charges nor deceive by the secret division of fees. As a laborer worthy of hire exact fair compensation but by open methods and with conscience void of offense toward thy fellow-man.

IX. *Obligation to One's Own.*

Take heed of the morrow for the sake of thine own flesh and blood. Therefore shalt thou keep orderly accounts, collecting from the full-handed just recompense for services rendered. To the poor and the families of deserving colleagues, thou shouldst account it a privilege to render faithful attention.

X. *Personal and Public Service.*

Remember thou art thy brother's keeper—physically in the measures and remedies advised for the prevention, alleviation or healing of disease; spiritually in the cheer thou bringest to heavy hearts and the courage thou givest to halting steps. So walking upright before man, mayest thou shew thyself approved unto God. Thus journeying toward life's end, if not singing with the Psalmist "My cup runneth over," thou wilt at least be sustained by the reflections of "A workman that needeth not be ashamed."

BRAIN ABSCESS

At the New Orleans session of the A. M. A., April, 1920, a very interesting paper on the surgical treatment of brain abscesses was presented by Adson of the Mayo Clinic, and the same is reprinted in the Collected Papers of the Mayo Clinic, Volume XII, 1920, just from press.

An interesting feature of the discussion is that the principle causes of pyogenic brain abscesses are middle ear diseases, frontal sinusitis and trauma, with the former predominating. In this connection statistics are quoted in which Heimann reports a series of 510 cases of brain abscess of otitic origin in which 457 were due to chronic otitis media and 173 to acute otitis media. This is significant evidence that brain abscesses are prone to occur in chronic suppurative conditions and may occur in cases of empyema, osteomyelitis and general septicopyemia as well as in cases of infection of the middle ear and frontal sinus. The abscess may arise from an infected area and extend into the brain by contiguity, such as those following infection of the middle ear or frontal sinus, or it may develop at a distance from its etiologic factor and be a part of a hematogenous or lymphatic infection. In the 26 cases operated at the Mayo Clinic, five were traceable to chronic otitis media, six to frontal sinusitis, two to frontal sinusitis with osteomyelitis, four to injury of the skull, five to chronic empyema, and one each to chronic empyema with septico-pyemia, pulmonary tuberculosis, lung abscess and bronchiectasis.

The clinical findings showed the average white cell count for the entire group as sixteen thousand, though in a few instances the leukocyte count was normal. Urinalysis was negative for all but four patients and those showed symptoms of acute nephritis. There was increased intracranial pressure in all. Spinal fluid and blood Wassermann tests were positive in two of the twenty-six cases, and this is considered interesting in that neither of these two patients had any corroborative symptoms of syphilis. The choked disc ranged from one to seven diopters. A resumé of the findings reveals urinalysis usually negative, a slight leukocytosis, and, if the abscess is unattended with meningitis or cortical encephalitis, a negative spinal puncture. One-third of the patients studied had choked discs, ranging from one to seven diopters, one-third had local tenderness over the abscess, and one-half had motor or mental impairment.

The duration of the symptoms varied from three days to three years, and each case followed one of three distinct courses. Sixteen patients had an average duration of symptoms of thirty-two days; four of these were operated on for brain abscess and promptly died. The five who recovered following a drainage of the abscess had an average duration of symptoms of six months; five patients had an average duration of twenty-seven months; two slowly recovered, and three died; two developed secondary infection and encephalitis, and one received an injury which ruptured an old abscess into the ventricle.

According to Adson a brain abscess may pass through three distinct phases: the initiatory, the quiescent, and the terminal. It should be operated on in the quiescent stage, not in the initiatory or terminal, as is frequently done. Of the patients seen at the Mayo Clinic, 16 were in the initiatory stage which did not pass into the quiescent stage. Those who were operated and recovered were treated in the quiescent stage when the immunity was the highest. In the terminal stages patients sometimes recover without operation, but the chances are greater that a secondary infection and death will occur.

In concluding, Adson says:

"1. The four principal etiologic factors in the formation of abscess of the brain are otitic infection, frontal sinusitis, injury to the skull, and hematogenous infection. Brain abscess is usually single, except when it is of hematogenous origin associated with a general pyemia, and then frequently it is multiple.

2. A brain abscess in its course may pass through the initiatory, the quiescent, and the terminal phases. The different stages can be determined more definitely from the history and duration of the complaint than from the physical findings.

3. If the abscess has developed by contiguity it should be explored through the area of infection, but if the abscess is remote from the source of infection, it should be explored and drained through an osteoplastic flap craniotomy.

4. Surgical treatment is of little value in the initiatory or terminal stages, or in the presence of meningitis, but it is of great benefit during the quiescent stage. If there is doubt as to the differential diagnosis of brain tumor and brain abscess in the quiescent stage, it is advisable to explore rather than to perform a decompression operation for intracranial pressure or to wait for terminal symptoms."

INTRAVENOUS MEDICATION

Before now we have had something to say concerning intravenous medication other than that included in the intravenous injection of arsphenamin or neo-arsphenamin, and in view of numerous letters of inquiry from readers concerning intravenous medication proposed by certain doctors who exploit dangerous methods of treatment and extol the virtues of drug compounds of secret composition, we feel justified in again calling attention to the subject.

Intravenous medication, as pointed out by the *Journal of the A. M. A.*, no matter what is used, is more or less dangerous. It should not be undertaken except under painstaking technique by one who has had training and experience in that class of work. Furthermore, the product injected should be definitely known as to composition and purity, and its effect also known as a direct result of experimental work by competent and trustworthy clinicians. At the present time a number of firms, as well as individuals, are advertising by circulars, and otherwise, various kinds of intravenous medication, and in practically every instance the firm or the individual exploiting such treatment is not one that through established reputation or experience in using the procedure or preparation recommended can be considered entirely trustworthy. Aside from this the preparation exploited is generally one of secret composition, and that of itself is sufficient to condemn it.

As a further contribution to our condemnation of certain forms of intravenous medication we herewith reproduce our answer to a letter of inquiry:

November 22, 1921.

—— — ————, M.D.,

DEAR DOCTOR:

Answering your letter of November 19 will say that we condemn all kinds of intravenous injections, or for that matter the prescribing in any way, of preparations of secret composition. Loffler's Intravenous Compound is included.

Many varieties of fakes and many species of quackery are offered to members of the medical profession for adoption and use. The really conscientious and ethical physician will refuse to use anything that is offered him unless proof of its value can be secured from a trustworthy source. The Council on Pharmacy and Chemistry of the A. M. A. is doing a wonderful work in placing its stamp of approval or disapproval on medical preparations or practices that are offered to the medical profession for adoption and use. You can not go wrong by following the advice or suggestions of that body. Every month we print a resumé of the work of the Council, and yet we know that some of our readers are conceited enough or ignorant enough to think that their judgment is superior to the judgment of some forty or fifty of the most eminent and qualified physicians in the medical profession.

Among the men exposed by the Council as quacks is Dr. Loffler, and among the fake preparations exposed is Loffler's Intravenous Compound. It would seem that any doctor who has any sense of honesty or cares to maintain a reputation for professional ability would refuse to have anything to do with Loffler's Intravenous Compound. However, it is quite possible that some doctors like to be humbugged, though it is more reasonable to suppose that some doctors, while not being humbugged themselves, are using a humbug to humbug their patients, and all for the sake of pecuniary gain!

Sincerely yours,
THE JOURNAL OF THE
INDIANA STATE MEDICAL ASSOCIATION.

RADIUM TREATMENT OF CANCER

In an editorial in the November issue of THE JOURNAL we quoted Deaver's recent statement to the effect that radium treatment of cancer has been disappointing and that he doubted if radium had produced *any* beneficial effect in the treatment of cancer. We questioned the truth of the statement, and called attention to the fact that while it may be that radium is not proving as valuable in the treatment of cancer as some have believed, yet it will take more than the conclusion of one man, no matter how eminent, to change the opinions of many serious workers and hundreds of cured patients concerning the effect of radium in the treatment of cancer. We now have a communication from Dr. Charles Goosmann, of Cincinnati, in which it is pointed out that Dr. Deaver evidently was referring to deep cancers, as the curative value of radium in skin cancers is everywhere acknowledged. In further discussion of the subject Dr. Goosmann says:

For a good many years it has been conceded that radiotherapy held out the only hope in inoperable cancer of the uterus. I have two cases that are well for 4 1/3 years and 1¾ years, respectively. Both had an exploratory laparotomy, but were too far advanced for any surgical treatment. In the one case the result was so good that a physician who saw the patient after the treatment declared there had been no cancer. A section of the tumor, however, had been retained.

In more recent times it has been conceded that the so-called border-line cases do better with radiation treatment than with surgery. The question today is whether, in early and operable cases, radiotherapy can give a larger percentage of permanent cures than operation. I believe this can be definitely answered in the affirmative. It must be borne in mind that removal of the uterus, followed by radium treatment, is not so satisfactory because

1. The intra-uterine application of radium permits much larger doses than can be tolerated in the vagina.

2. Radium inside the uterus is placed at about the center of the pelvis and therefore can reach the deep structures better.

3. It is an open question whether removal of the uterus does not frequently scatter the cancer cells throughout the pelvis.

Radiotherapists for some years have been very conservative in their statements. In fact, most of the published claims for this form of treatment in operable cases have been made by surgeons, who have taken it up. Here there could be no claim of prejudice, since obviously, they could take it or leave it alone, and the results had to be very encouraging to

overcome that trait of humanity which "makes us rather bear those ills we have, than fly to others that we know not of". It would be strange if a treatment that cured even one advanced and inoperable case could not succeed a good deal better with early cases.

Recasens[1] of Madrid has treated over 400 cancers of the cervix uteri with radiation in the past seven years, and believes that radium plus x-ray is undoubtedly superior to any other method of treatment.

Heyman[2] of Stockholm, Sweden, considers 20 percent a liberal estimate of *operative* cures. He has 66 cases treated with radiotherapy, of which 28.8 percent have been well for five years. All of these were inoperable except seven, of which number five (44 percent) are well.

Opitz[3] of Freiburg, Germany, judging from the literature and his own results, which are constantly improving, feels convinced that uterine cancer can be permanently cured with radiation alone, and probably in a larger percentage than with operation. He, therefore, does not operate them any more.

Seitz[4] of Erlangen, Germany, after discussing his results, says: "It is, therefore, comprehensible that we have come to the conclusion, at first hesitatingly, but now with more assurance, to treat all uterine cancers with radiotherapy, either radium and x-ray combined, or the new method of x-ray alone." (He does not believe radium alone quite so satisfactory.)

That these opinions are not confined to foreign observers can be easily shown. Ransohoff[5] was one of the first to emphasize the advantages of radium treatment as compared with operation, in early cancer of the cervix. Recently Duncan[6], Barrow and Frank[7] and Clark and Keene[8] have expressed similar opinions. All but one of these American writers are surgeons; only one of them is primarily a radium therapist. I will quote from Clark and Keene: "In comparing the vast outlay of surgical effort put forth in the latter class of cases with the great dangers attending the radical operation, as to both mortality and disabling results, we feel convinced that the time has about, if not quite, arrived when we shall cease to speak of any operable cases of cancer of the cervix, but shall submit them all to irradiation. Certainly our results have led us convincingly in this direction. As the palliative results have been so excellent and, as our statistics now appear, the actual cures have been so relatively large in the hopeless cases, it would appear illogical to submit the early operable cases to the great dangers of surgical intervention and reserve only the inoperable case for irradiation. While we still discuss operability, we are turning to this method of procedure in such a small minority of cases in our clinic as to carry our statistics in this line almost to the vanishing point.

SOCIALIZING MEDICINE

[Bulletin of the Wayne County (Detroit) Medical Society]

A member of the Legislative Committee of the Michigan State Medical Society has the following to say concerning efforts that are being put forth to socialize the practice of medicine:

"If we are fighting today with our backs to the wall to prevent the socialization of medicine and the degradation of the individual, it is because in our race for bigness, we have permitted our moral and intellectual clearness to be befogged. As individual practitioners of medicine, we have boasted of our great national organization and its great Journal. We took pride in the fact that the A. M. A. was worth almost a million dollars in quick assets, and that the income of its Journal was reaching toward that princely sum of one million dollars for one year's income. We bragged that our association numbered its members by the thousand, but we forget to ask Huxley's pertinent question, 'What have we done with it?'

"When we cast up accounts, our pride is due for a hard fall.

"We have permitted our great national organization to become the plaything of 'paper philosophers', men too rich or too tired, or too lazy, or too ambitious to tread the thorny path of the practice of medicine; men who prefer the job of telling us what to do, to doing it themselves; men who chafe at the long, tedious apprenticeship of the physician and surgeon but prefer short cuts to positions under various names; men whose sole aim is to sit on a throne, directing and controlling a horde of medical slaves who are to do all the work, take all the responsibility, but to pass up the rewards. And all of this has happened, because we have been too busy growing big to be sure that we were growing just. We gave these men power and, like Oliver Twist, they wanted more. It is a human failing, for all men are potential despots at heart.

"We have seen our good money paid out in salary to an avowed apostle of Compulsory Health Insurance by the Council on Health and Public Instruction of the A. M. A., at the bidding of a chairman who was a shining light in the councils of the American Association for Labor Legislation, sponsors for the socialization of medicine. And we were asked to accept the report of this apostle and his brother of the A. A. L. L. as being disinterested.

"This year, we were treated to the spectacle of a leader of the A. M. A., a gentleman who for years has been a power in shaping the policies of the A. M. A. and its Journal, appearing before the House of Delegates to repudiate a speech, favoring Compulsory Health Insurance, which he had made some time ago and which

had been printed in the *Journal of the American Association for Labor Legislation*. He did not claim that he had not been fairly reported, but now that he was a candidate for re-election as Trustee, and the A. M. A. had gone squarely on record as opposed to Compulsory Health Insurance, he wanted to take it all back. A man has a right to change his mind, but to the disinterested observer that change would have been in the better taste if announced at a time when the candidate was not looking for votes.

"And to add to the strangeness of the situation, we found men who were openly favoring 'State Medicine' on the score that it means bread and butter to them, jumping in to back up this candidate who was recanting the very opinions his backers were favoring. These Public Health Officials waxed indignant as they denounced the men who had brought out this speech of the candidate's in favoring socialization. They called upon the House of Delegates to try them for treason and to boil them in oil if necessary. And what had these men done who were being thus roundly abused? They were simply trying to find out whom this candidate would represent, if elected. He had preached Compulsory Health Insurance in the A. A. L. L. Journal and the question of moment was, will this candidate, if elected, represent an interlocking directorate of the American Association for Labor Legislation and the A. M. A., or will he represent the overwhelming majority of the medical profession who are opposed to the measures for which the socializers of medicine stand? The candidate was elected after a hard fight. Time will tell, but vigilance alone will be the price of knowledge.

"We have lived to see Johns Hopkins fix a fee for a week's care by a physician at $35, a salary which many a taxi driver will scorn. All these things we have seen, and the question is, what are we going to do about it? That no man shall be able to plead ignorance of existing conditions is the purpose of the BULLETIN. The profession must fight. If necessary, take a beating and fight again. Our socializers hope to tire us out, but once we drive them into the open, take from them their brazen shields of wealth, position and reputation, behind which they are hiding, then and only then, will the overwhelming majority who pay the freight come into their own again and the A. M. A. represent the physicians of this country and not be the mouthpiece of our 'Paper Philosophers'."

DRIFT TO SOCIALISM

Now that the Sheppard-Towner maternity—so-called—bill is a law by virtue of the President's signature, the American people would do well to ask themselves whether the swing to socialism has not gone quite far enough, and whether it should not be stopped. The bill in question is thoroughly bad. But it is now a law, so there is no call for a further discussion of it. Its effects, or non-effects, will be carefully watched. There will be great pressure on the legislatures of the states to appropriate large sums of money in order that they may get some of the money to be appropriated by the federal government. Such a partnership is dangerous, and fraught with great possibilities of evil.

But the broader question is whether our people are to take care of themselves or be taken care of by the government; whether they are to manage their own affairs, or permit the government to do so; whether they are to be the independent, individualistic, resourceful people they used to be, or mere wards of the central authority. The issues are weighty, involving as they do both the character of our government and institutions, and of our people. Every scheme of governmental aid ought to be viewed with grave suspicion, for all such schemes involve fundamental political principles.

So it is suggested that the American people should, if they would preserve their liberties, look to themselves and their government, and resolve that they will not tolerate in the future any policy that is inconsistent with the spirit of American institutions, or with the principles on which they rest. The tendency toward socialism is strong and the appeal of socialism is evidently most alluring to many of our people. This is shown by the character of our tax legislation, tariff policies, and class legislation of various sorts. There is no danger to be apprehended from Socialists as such, but there is real peril in socialism, which is making great strides, though it is not by many understood to be socialism.—*Indianapolis News*, Nov. 24, 1921.

THE LORENZ FIASCO

A few weeks ago Professor Lorenz, the famous Vienna orthopedic surgeon, who made quite a reputation and a very large fee for himself about twenty years ago by treating the daughter of P. D. Armour, of Chicago, landed in this country and announced that he had come here to repay a debt to America by offering his services gratuitously to the crippled children of America. He announced that he would hold clinics in the various cities of the country, and

he began his work in New York where hundreds and perhaps thousands of crippled children besieged the hospital where he was working in response to the advertising of the plans as given in the daily press. As we pen this editorial we learn that Professor Lorenz has abandoned his plan to continue clinics in this country, and all because his work has not received the sanction of some of the leading medical men of America. As to be expected, some of the lay publications are condemning the medical profession of the United States for having opposed Professor Lorenz, or perhaps for not having encouraged him in his work.

A little analysis of the facts pertaining to this episode may clear the atmosphere somewhat and show that Professor Lorenz is not wholly altruistic in his motives. When he came here over twenty years ago for the purpose of treating the Armour girl he probably was one of the best orthopedic surgeons in the world, he conducted himself in an ethical manner, his visit here was not opposed, and he was given a cordial welcome by medical men wherever he went. In fact he was given the opportunity of not only demonstrating some of his own orthopedic methods but he courteously was placed in a position where he could make thousands of dollars in this country by treating cases in some of our wealthy families. Since that visit orthopedic as well as all other surgery in the United States has made great advances, in fact now leads the world, and at the present time there are several surgeons in New York, as well as surgeons in every large city in the United States, who can do anything that Professor Lorenz can do. They not only are capable of doing bloodless surgery as well as it is done by Professor Lorenz but they are as willing to do it gratuitously for America's worthy poor. They are doing it daily in all of our large clinics, but they are not doing it with a blare of trumpets nor are they asking that their work be heralded through the metropolitan dailies as miraculous or even unusual. In fact it would be exceedingly distasteful to them were they to be advertised in the daily papers and in the moving pictures as Professor Lorenz was advertised.

It is the height of absurdity for anyone to think that Professor Lorenz is in this country because he so loves the American people that he wants to repay any debt of gratitude that he or his countrymen may owe. We feel satisfied that few if any Austrians consider that they owe us anything in gratitude or in money. They despised us for going into the war, and they attribute their defeat to the fact that we finally did go to the assistance of their enemies. Deep in his heart Professor Lorenz entertains no better feeling for us than the rest of his countrymen, even though now, with the war over and his purse depleted, he is quite willing to assume a suave demeanor and cultivate our friendship for the dollars to be gained thereby. Professor Lorenz knows that the crippled children of Austria, and particularly in his own city of Vienna, need his services right now far more than do the crippled children of America, and if he really possessed the altruistic motives in furnishing his services gratuitously he would be at home where he is so sorely needed, rather than in America where he is not needed and where the work that he has been doing can well be carried on by American surgeons who are as competent as he. The truth of the matter is that Professor Lorenz came to this country to recoup his fortunes, and he knew that he could depend upon the public press to advertise him well if he came in the name of charity. He knew that the advertising received would bring to him not alone the worthy poor but the rich as well, and that the latter would afford him princely fees for services rendered. Therefore the American surgeons in New York, Philadelphia, St. Louis and Chicago, who are reported to have been opposed to the Lorenz clinics in this country, have just reason for presenting a cold shoulder to such spectacular performances undoubtedly designed and carried out for personal gain.

There is no occasion for the deserving poor being uncared for in this country. There isn't a reputable surgeon in America who doesn't do a great deal of charity work and who is not willing to do a great deal more if approached in the proper manner for the services. Aside from this there are hundreds of well trained young medical men in all of our large cities who consider themselves most fortunate if they are able to gain experience by caring for the deserving poor who may apply in person at the clinics for aid or who may be brought there by the various organizations connected with social service. The great trouble is that our social service in the cities is not developed nor managed as it should be, and in consequence our medical men are imposed upon by the well-to-do, and communities are pauperized by the bestowal of gratuitous medical and surgical services upon the unworthy who do not hesitate to take advantage of it when the really needy hesitate about asking for such help. However, there are competent surgeons in New York who are doing as much and as good charity work as Professor Lorenz attempted to do, and they neither ask nor covet the advertising that has been given Professor Lorenz. When they do this day in and day out in an ethical and modest manner, is it any wonder that they do not look with favor upon the Lorenz fiasco?

DEATH OF DR. KIMBERLIN

As we go to press we learn of the tragic death of Dr. A. C. Kimberlin, of Indianapolis, which occurred accidentally, on December 14, while he was on a hunting trip in southern Indiana.

Perhaps no man in the medical profession of Indiana has been more loved and honored by his confreres than Dr. Kimberlin. He was president of the Indiana State Medical Association in 1913, and in making the announcement at that time we called attention to the fact that Dr. Kimberlin's career represents in a striking manner the romance of American life. Leaving the farm when a mere youth because he was dissatisfied with the opportunities it afforded for his future, he went to Indianapolis without capital other than sturdy parentage, a healthy body, a common school education, and a determination to succeed. A three years' course in the Indiana Medical College and one year's internship at the Indianapolis City Hospital constituted his immediate educational equipment for the practice of medicine, but with him, as with every other man who succeeds in medicine, the real school began when he left college and the hospital and began the practice of his profession. He was an indefatigable student and keen observer. His frequent attendance at clinics both in this country and abroad, his deeper interest in the success of the Indianapolis Medical Society, of which he had been both president and secretary, was inspired largely by a desire to become informed of the advances in scientific medicine. Although occupied by the exacting duties of a large private practice, Dr. Kimberlin devoted a great deal of his time to the teaching of medicine, and at all times was deeply interested in the success of the Medical Department of the Indiana University in which institution he held the chair of clinical professor of medicine. In addition to his official activities already mentioned he found time to serve upon the Indianapolis City Board of Health, to be actively identified with all of the prominent medical associations of local and national character, and for over twenty years was on the clinical staff of the Indianapolis City Hospital. In recent years he turned his attention exclusively to the subject of internal medicine, and he established for himself a reputation as a careful, painstaking and competent clinician and consultant. Probably no medical man in Indiana has been more loved by his confreres, for coupled with a pleasing personality he exhibited a sympathetic interest in the welfare of his associates, and at all times a sterling character so much admired among all men. His untimely death at fifty-eight years of age is a shock to all who knew him, and the medical profession of Indiana has lost one of its truly great men.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

To all our readers: A Merry Christmas and a Happy New Year!

LOST—Dr. Luke P. V. Williams of Greenwood is searching for a pair of twin boys, Lester and Chester Ford, seventeen years of age, who have disappeared from their home. Any information concerning their whereabouts will be gratefully received.

EACH one of our readers should read the department in THE JOURNAL devoted to Propaganda and Reform. In it will be found much valuable information concerning not only reliable and trustworthy preparations, but fake and near-fake remedies as well.

IT may not be out of place to call attention to the fact that those who fail to pay their medical society dues on or before February 1 are delinquent, and cannot receive the benefits of the Association and especially the protection afforded by Medical Defense. Why wait until the last minute and thus run the risk of being penalized unnecessarily?

WE know that the county medical society secretaries now are trying to collect dues for the coming year. Why not surprise your secretary by sending in your dues without being solicited? You know that your dues should be paid on or before January 1, so why not pay them now? It will save your secretary work, and his job is a thankless one anyway.

HERETOFORE there has been some complaint that some county medical society secretaries do not send dues to the Secretary of the State Medical Association as promptly as they should. This means that some members may become delinquent through no fault of their own. Members of county medical societies should remember that the county secretary, chosen by themselves, is their own representative, and the State

Association cannot be held responsible for dereliction of duty on the part of the county medical society secretary.

THE membership list of the Association, by counties, is published in this number of THE JOURNAL. In some instances members who are credited with membership in a county medical society are non-residents, but as far as possible the post office address is given with the name. The list has been checked by Secretary Combs and therefore ought to be correct. Incidentally it forms a part of the mailing list for THE JOURNAL and if any members desire corrections made they are requested to notify the editor of THE JOURNAL to that effect.

DOCTORS, lend your support and assistance to the Fourteenth Annual Christmas Seal Sale. What is it accomplishing? Listen: It is saving 75,000 lives a year. It is providing hospital care for 100,000 tuberculosis patients a year. Nearly 75,000 children are being restored to health in open air schools. Over 5,000,000 calls a year are being made by 5,000 public health nurses. Practically all of our 110,000,000 Americans are being educated to better health. About 7,000,000 school children are learning correct health habits through the Modern Health Crusade.

ONE or two new chiropractic colleges have been started in Fort Wayne, and they now are so numerous in that city that it is hard to keep track of them. The number is not exactly known as we have had no official reports during the last forty-eight hours. Incidentally, it is known that the chiropractic signs in the city of Fort Wayne far out-number the signs of all real doctors put together, but the latest accounts indicate that the real doctors are doing as much work as ever before. It is a known fact that the chiropractors are warring among themselves, and one suit by some of the students threatens to close up one of the chiropractic schools. Perhaps if they are let alone they will "hang themselves with their own rope".

CHRISTMAS seal your Christmas mail! Since 1908, when the first annual Red Cross Christmas seal sale was inaugurated, the national, state and local tuberculosis associations have been constantly reducing the death rate from tuberculosis which, at that time, was nearly 200 for every 100,000 population. Now—1921—this human loss has been reduced to approximately 125 for every 100,000 people, a saving of 75,000 lives annually. The use of Christmas seals on your mail, (1) helps provide care and treatment for those who have the disease: (2) helps prevent those who are infected with it from breaking down with active tuberculosis; (3) helps control the spread of infection from those who have it to those who do not have it. Christmas seal your Christmas mail!

THE chiropractors are getting so thick, and the "business" that goes to chiropractors has to be spread out so thin in view of the numbers of those who grab for it, that it has become necessary to make personal solicitations for work among those reported as sick or disabled from any cause. Soliciting "business" by letters, and even by telephone calls, is not at all unusual, and we have heard of one afflicted family that received several letters from as many different chiropractors asking for the privilege of making "adjustments" with a view of accomplishing a cure. The pathetic feature of this whole nauseating business is that the ignorant and the poor for the most part are the ones that are deluded and swindled, and they are the ones who can least afford it.

WE desire to call the attention of our readers to an advertisement which appeared in the November number of THE JOURNAL in which a well known pharmaceutical house say in their advertising "Prescribe Council Passed Products", meaning of course that physicians who are wise will use only those pharmaceutical specialties that have been examined and approved by the Council on Pharmacy and Chemistry of the A. M. A. That is the right kind of talk, and we are especially pleased to note that the more progressive manufacturers of pharmaceutical specialties and biological products are coming to the conclusion that not only is the Council an excellent body of clinicians and investigators whose approval is worth securing, but that the rank and file of the medical profession will be wise if the Council's findings are heeded.

THE Sheppard-Towner bill in its amended form has passed Congress and been signed by the President. Therefore it is now a law of the land. It appropriates a large sum of money, a good portion of which is devoted to administration expenses. Nothing is provided for the care or treatment of the maternity case, in reality the one that the bill was supposed to aid and protect. It was opposed by an almost united medical profession, by many women's clubs, and by many civic organizations. In the main it is a "pork barrel" measure, and the functioning which the bill provides for is placed in the hands of a committee the majority of whom are laymen. Unquestionably the bill as passed provides for a wasteful expenditure of money without adequate return, and to top the whole thing off

its operation is not placed in the hands of the Public Health Service where it belongs. Could anything be more demonstrative of what politics will do?

THE *British Medical Journal,* in launching a campaign to better the personnel of the medical profession, makes the statement that "No one should think of entering this profession who is unprepared to spend $75,000 on his medical education". Is it possible that England has not heard of chiropractic for the cure of all diseases and ailments, from cancer to chicken-pox, the science of which cult can be learned in from three to six months, at a cost not to exceed $100! Why spend $75,000! England indeed is "behind the times" if she still believes in long medical courses covering physiology, anatomy, bacteriology, histology, pathology, etc., etc., when such knowledge is entirely superfluous, and all that is necessary is a little exercise and training of the fingers to "manipulate" the vertebræ for the cure of any and all diseased conditions! Someone should advise the *British Medical Journal* of its terrible error in making such a statement!

NEVER before have doctors as well as others been importuned so much and so strongly to invest earnings in questionable enterprises ranging all the way from certificates of stock in imaginary oil wells to promotion stocks in industrial enterprises. A good rule to follow is the one promulgated by Better Business Bureaus everywhere that say "Before you invest, investigate". The best and only way to test out an investment is to measure it according to the standards of safety. Take nothing for granted. Check up or prove what the salesman tells you. Remember that safety of principal is the first consideration, and big returns are seldom secured from enterprises whose stock is peddled. Remember that the safest investments are those that return a moderate income. A safe rule to follow in case one hasn't the time to investigate thoroughly the proposition that is offered is to ask your banker *if he will recommend the buying of the stock that is offered.* Your banker may be one of the "suckers" that occasionally bite a well-baited though treacherous hook, but he seldom if ever will advise a client to do anything other than pursue a perfectly safe course.

FORT WAYNE seems to be a fertile field for the establishment of chiropractic colleges. Within the last few months several new chiropractic schools have blossomed out, the exact number not being known as we haven't received the returns during the last day or so. Already graduates of schools that have been in existence only a few weeks are flaunting their diplomas and soliciting "business" with a persistence that would do credit to a fake mining stock salesman. Incidentally these chiropractic schools are about to deprive the public of some reasonably good janitors, barbers, and even common street laborers, many of whom are looking forward to the time when they can make "easy money" through chiropractic "adjustments" the knowledge of which can be obtained in a few weeks of indifferent training. Even the elevator boy in one of the local hospitals in Fort Wayne, scarcely out of short trousers, and never having gone beyond the ward schools, proudly volunteered the information that in six weeks he would be a "chiropractic doctor", and then would not have to run an elevator. However, we predict that chiropractic, which has gone up like a sky rocket, will come down like the stick. Anything so idiotic as chiropractic is not going to last, but the trouble of it is that when chiropractic goes, something equally as idiotic and inconsistent will spring up to take its place. Thus the need of restrictive legislation to protect the people from such fakes.

The annual meeting of the Indiana Academy of Ophthalmology and Otolaryngology will be held at the Claypool Hotel, Indianapolis, January 18, 1922. Following is the program:

MORNING SESSION

9:00 A. M.

Parlor B—Claypool Hotel

1. Secretary-Treasurer's Report.
2. Committee Reports.
3. New Instruments.
4. Case Report—DR. C. J. ADAMS, Kokomo.
5. Case Report—DR. J. W. CARMACK, Indianapolis.
6. Comparative Anatomy of the Eye. Gross Pathology. Illustrated by Mounts.—DR. GEORGE F. KEIPER, Lafayette.
7. Election of Officers.

AFTERNOON SESSION

1:30 P. M.

Parlor B—Claypool Hotel

1. President's Address.
2. Lip Reading for Hard of Hearing Adults. By Invitation.—MISS GERTRUDE TORREY, Chicago.
3. Subjective and Objective Nasal Symptoms—W. A. HOLLIS, Hartford City.
4. Hereditary Sub-Luxation of the Crystalline Lens—DR. F. MCKAY RUBY, Union City.
5. Persistence of the Embryonic Fibro-Vascular Sheath of the Lens. Illustrated by Lantern Slides.—DR. E. J. LENT, South Bend.
6. Toti Mosher Operations on the Tear Sac—DR. J. F. BARNHILL, Indianapolis.

EVENING SESSION

Dinner.

Speaker—DR. HARRY POLLOCK, Chicago.
Subject: "High Spots in Otolaryngology."

A NEW YORK doctor possessing a rather unsavory ethical reputation is getting a lot of free newspaper advertising by giving out interviews concerning his removal of tonsils by the use of x-rays. Incidentally it may be mentioned that some of the most noted clinicians, whose opinions are respected by the medical profession, have tried x-ray therapy for enlarged tonsils and found the treatment disappointing and in a few instances positively harmful. There was a time when the high frequency electrical current was recommended by various enthusiasts as very valuable in the treatment of everything from appendicitis to ingrowing toenails, not omitting enlarged tonsils, and while the high frequency current no doubt is very beneficial in a limited field yet we seldom hear of it any more. X-ray therapy, and still later radium therapy, has been going through similar processes, being heralded by enthusiasts as applicable in a very large variety of diseases and abnormal conditions, but eventually may be found to have but a limited sphere of usefulness. Both radium and the x-ray are now doubted as being efficacious in anything more than a very limited number of malignant conditions, and quite recently Dr. Deaver, the well known Philadelphia surgeon, has felt called upon to say that he doubts if radium ever has produced any proven beneficial results in the cure of malignancy. However, x-ray and radium therapy will reach their proper status before long, like everything else that is tried as a curative agent, and let us hope that they will be found valuable in the treatment of some diseases or abnormal conditions even if they fail to remove tonsils.

OUR readers may know that the Walker Pharmacal Company is exploiting a proprietary preparation of secret formula called "Hymosa" as a remedy for acute and chronic rheumatism. In the circulars being sent to Indiana physicians are two testimonials, one by Dr. F. A. Sauer, Baltimore, Maryland, and we are unable to find such a name in the A. M. A. directory. That is about how most testimonials turn out when investigated.

Irrespective of the irrational and unscientific practice of prescribing proprietary remedies of secret composition we desire to call the attention of our readers to the fact that the Walker Pharmacal Company is the one that has been guilty of fraudulent claims concerning the virtues of several preparations, notably "Succus Cineraria Maritima," advertised as a remedy for absorbing various forms of cataract. This is the preparation that the government analyzed and afterwards made a report concerning it in which it was stated that the claims made for it "were false and fraudulent in that the same were applied to the article knowingly and in reckless and wanton disregard of their truth or falsity." The company entered a plea of guilty and was fined, but still they continue making similar claims to the medical profession and public. As we stated in THE JOURNAL, December, 1920, "Two things are quite evident to us: first, that the federal punishment was not sufficiently severe and should be repeated in such force that future activities will be found too expensive; second, that there are enough doctors of the credulous type who support these frauds so well that the exploiters can afford to pay a federal fine occasionally and still be ahead of the game."

As a memorial to James Whitcomb Riley nothing could be more fitting than the establishment by Indiana people of a hospital for children. The only objectionable feature in connection with the plan proposed is that covered by the provision made by the last Indiana legislature authorizing the establishment and maintenance of such a hospital providing that *all* (italics ours) of the children of the State of Indiana who need medical attention *may* (italics ours) be admitted *without cost* (italics ours) to them as rapidly as facilities will permit. The law even says that the children whose relatives are able to pay for the care at the hospital may do so, but this is not compulsory. The State is to provide funds for equipment and an annual appropriation for operation, thus assuring funds for permanent maintenance. All of the property will be owned by the State of Indiana. Already the State has provided fifty thousand dollars a year for operative expenses, but the James Whitcomb Riley Memorial Association has pledged itself to raise a million dollars for the purchase of grounds and erection of buildings. It is hoped that the feature of the law which says that all of the children of the State who need medical attention *may* be admitted without cost, etc., shall be construed in such a way that the *indigent* children shall be the only ones admitted as free patients. All others should pay according to their means, for there is no reason why the State should pauperize the community. No finer tribute to Riley could be offered than the establishment of a children's hospital, and such an institution is needed for the purpose of giving appropriate attention to the crippled and sick poor children of the State. However, there is no need of making a charitable institution, for which there is urgent need, a place where the well-to-do can go for the purpose of avoiding the payment of just fees for attention and care.

THE following excerpts from letters written after the publication in the *Woman's Home Companion* of Ernest Harold Bayne's unbiased

opinion on vivisection are sufficiently condemnatory to make the average person appreciate the dishonesty of the anti-vivisectionists, and the fallacies of their claims:

The trouble with the anti-vivisectionists is that they are not only dishonest but wilfully dishonest. They picked out one sentence from a paragraph in my address, "In the Time of Henry Jacob Bigelow," given before the Boston Surgical Society in Boston, on June 6th, and exploited it for their purposes, ignoring the fact that the impression they produced was quite contradictory to the views expressed. The truth is not in these people.—W. J. MAYO, Rochester, Minnesota.

What animal experimentation has accomplished for the benefit of mankind may be inferred from the list of diseases which are no longer the destroyers and terrors that they were: Smallpox, cholera, typhus fever, typhoid fever, puerperal fever, yellow fever, cerebro-spinal meningitis, diphtheria, hookworm disease, and malaria. All these diseases would have remained the terrible scourges they used to be, were it not for animal experimentation, and the progress in curative and preventive medicine which it has made possible.—CHARLES W. ELIOT, President Emeritus of Harvard University.

I am glad that you brought out the fact that those who are opposed to vivisection are constantly resorting to falsehood to support their case. It is a weak cause, indeed, which demands the desertion of moral principles for its presentation and defense.—C. I'. TIVNAN, S. J., President Fordham University.

Animal experimentation is of the highest importance to the welfare of the livestock industry, and thus, indirectly, as well as directly, in its relation to our knowledge of human diseases, of very great importance to the welfare of humanity. * * * In the light of my knowledge of what animal experimentation means to human welfare, I can say, without extravagance, that most terrible consequences would inevitably follow upon the general adoption throughout the world of the program of prohibition and regulation of, and interference with, animal experimentation that is advocated by the opponents of this fundamentally important means of the scientific investigation of disease.—J. R. MOHLER, Chief of Bureau of Animal Industry of the U. S. Dept. of Agriculture.

COMPULSORY Health Insurance, State Medicine, Venereal and other free clinics, and many other social uplift schemes requiring the energy and thought of the members of the medical profession are but stepping stones to socialistic medicine, which not only puts individual incentive and practice out of commission but will place the whole public under the rule of inefficiency. Perhaps we hear someone say, "Well, what is to be done?" to which we answer, in the words of the *Illinois Medical Journal*, "quit giving approval to these various cross-eyed medical uplift schemes advocated by erstwhile reformers and public welfare peddlers who usually see in their schemes some avenue for profit." Some of our medical men who have acquired wealth and social position seem to think that it is quite the proper thing to approve of these various uplift schemes in order to bask in the sunshine of the mighty, forgetting that in the security of their own economical position they are tramping upon the toes of their less fortunate brethren. In reality this "dear public" and "love of humanity" stuff is greatly overworked. The practice of medicine is a vocation, the following of which should be as much entitled to decent remuneration and consideration as any other vocation. It is as deserving of as much consideration as that of plumbing or bricklaying, but usually receives less. The difference between members of the medical profession and members of the plumbing and bricklaying crafts is that the former has no standing commercially or politically and is unable to secure any consideration in its demands for right or justice, whereas the latter through their unity of purpose and insistent demands for recognition secure what they are after and overthrow everything in opposition to it. What we need is a little more brotherly feeling for each other, and a little more consideration for our co-workers, and when we are looking out for the purely selfish interests of the members of the medical profession in adding to their welfare we also are adding to the welfare of the public, which is served by the medical profession.

THE necessity of adequate preparation and the folly of trying to present a subject extemporaneously, as applied to the average speaker, was never more forcefully demonstrated than at the postgraduate course given in connection with the recent or Philadelphia session of the Academy of Ophthalmology and Otolaryngology, when each man on the program was given a specific time for the presentation of his subject in a comprehensive manner and curtly informed that any additional time granted him would be at the expense of the next speaker. While many of the speakers had prepared their work in the form of a written address or carefully prepared notes, and due regard paid to conciseness of statement and avoidance of repetition and the addition of irrelevant subjects, a few of the speakers lamentably failed because they had not prepared themselves suitably and did not conform to the first principles of good public speaking. Iteration and reiteration, too much attention paid to inconsequential and irrelevant things, and perhaps a slow, hesitating delivery occasionally spoiled what should have been a profitable hour for the hearers. In a few instances some very instructive lantern slides or very creditable demonstrations were held until the last, only to be rushed through or omitted altogether on account of lack of time.

There are altogether too many men trying to present addresses or talk before medical societies without adequate preparation, and without any idea as to how or in what manner the subject is to be presented. The good extemporaneous speaker is an exception, and a carefully

prepared paper or address is appreciated far more than a disconnected, rambling and superficial talk, no matter how competent the speaker may be to talk upon the subject selected. Brevity—and conciseness consistent with lucidity—should be cultivated by all speakers, and no man is justified in accepting an invitation to appear before an audience unless he has made such preparation as will enable him to present his subject intelligently and concisely within the time allotted him. This means preparation in both the selection of material and the manner of presenting it. Any other course means an injustice to speaker and to audience.

"THOSE persons who are advocating the establishing of a federal department of public welfare are many of them no doubt well intentioned and sincere, yet it is a pity that efforts of this character cannot be directed toward the furtherance of plans more practicable and salutary. This country does not need a department of public welfare, such as is proposed, and its establishment would be bitterly resented as a bit of rank paternalism. This thing of attempting to direct American family life and to turn out citizens molded like ice cream flowers in the fashion designed by a lot of faddists does not fit in well with the popular conception of liberty and freedom of action. We have with us today far too many people who are endeavoring to shape the lives and govern the conduct of other people, and to establish a federal department which shall give these endeavors the sanction of the law and the power of authority is coming it entirely too strong to suit people who fled from the old world to escape just that sort of meddlesome interference, and those who having lived here all their lives have become imbued with the idea that those lives are theirs to live as they please so long as they please to live within the law. It is all very well to tell us that these benevolent friends who wish to mold us have "advanced ideas" and are loving benefactors, yet men, and women, too, for that matter, echo in their hearts the longing of the harassed and pestered British soldier who cried:

> "Take me somewhere east of Suez
> Where the best is like the worst,
> Where there ain't no Ten Commandments,
> And a man can get a thirst."

"Not an ennobling or uplifting sentiment truly, but a very natural protest against the bullying regulations of those who spend their lives seeking to better others by submitting them to Procrustean standards of reform. The truth of the matter is that the American people have been regulated enough for a while and they want to be let alone.

"There is another objection to this proposal and that is the tremendous expense involved. It proposes a payroll as long as the moral law, and would take care, at public expense, of all of the uplifters, reformers, freaks, and faddists in the whole country. This is no time to take on additional burdens in a financial way. Let us first see our way out of this dismal swamp of disastrous debt into which we were recently plunged by the forward looking gentlemen who thought so much of humanity that they forgot the people of the United States."—*Fort Wayne Daily News and Sentinel.*

IT is questionable if medical school inspection in some localities is not more harmful than beneficial. When the inspection is made by competent and well trained physicians it ought to accomplish great good. On the other hand, when it is carried out as it is in some localities in Indiana, by doctors having little medical education and training, by Red Cross or other nurses who profess to know more than they really do and often are guilty of over-officiousness in offering advice and suggestions that are irrational and not in keeping with established medical or hygienic rules, the medical inspection is very apt to lose most of its potent force for good. For the most part medical inspection in the cities is fairly good, though even there there is room for great improvement, because too much of the work is delegated to those not properly trained for the work, and we refer especially to the examinations that are entrusted to nurses and non-medical clerks or other employees connected with the Public Health Department. In the country districts medical inspection of schools is largely a farce, except in those rare instances when a real up-to-date and progressive physician is carrying on the work. In some of the counties of Indiana we know that the medical inspectors are more or less ignorant and poorly trained medical men who still believe that children in the public schools contract consumption when the school rooms are ventilated or when sleeping with the windows open, and still maintain the ignorant and untenable opinion that tonsil and adenoid tissue was put in the throats of children for a purpose, and that if there is any excess of it, it can be reduced by "absorption treatment". In Indiana there are even some nurses, presumably trained in the up-to-date methods, who are equally as lame as the doctors in possessing modern medical knowledge, and whose suggestions and advice to the parents and children of some communities are positively pernicious. All of which reminds us that this railroading of people and especially school children into beliefs promulgated by a species of socialistic medicine, is but the beginning of ill effects which will result if the plan is carried still farther and the public is asked to go to the State for its medical advice and attention. We have no criticism to offer of the

general plan of having school children inspected upon entrance to our public schools, and in a measure under the control of medical inspection at all times, so far as it pertains to limiting transmissable diseases among school children, but we do object to the practice of making a farce of medical inspection by placing it in the hands of incompetents.

DEATHS

CLARENCE P. COLBURN, M.D., died at his home in Richmond, November 17, at the age of sixty-two years. Dr. Colburn graduated from the Miami Medical College at Cincinnati in 1883.

BENJAMIN H. COOK, formerly of Indiana, died at his home in Los Angeles at the age of sixty-three years. Dr. Cook graduated from the Medical College of Indiana at Indianapolis in 1885 and was a member of the Madison County Medical Society, the Indiana State Medical Association and the American Medical Association.

H. H. MILLER, M.D., of Galveston, was instantly killed, November 21, when the automobile which he was driving was struck by a Pennsylvania train. Dr. Miller was fifty years of age. He graduated from the Louisville Medical School in 1897 and was a member of the Cass County Medical Society, the Indiana State Medical Association and the American Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in *The Journal of the Indiana State Medical Association*. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

DR. G. R. COFFIN, of Monticello, has been elected mayor of that city.

THE Jasper-Newton County Society held a meeting at Mt. Ayr on October 28.

ROOSEVELT Hospital celebrated the fiftieth anniversary of its founding November 2.

DR. M. V. B. NEWCOMER, of Tipton, celebrated his eighty-fifth birthday October 30.

DR. CLAUDE LOMAX has moved to Holland, Indiana, where he is practicing medicine.

CONTRACTS have been let for the erection of the Blackford County Hospital at Hartford City.

DR. RICHARD A. POOLE has been appointed superintendent of the City Hospital in Indianapolis.

DR. CLYDE C. BITLER underwent an operation for appendicitis at the Clinic, Newcastle, October 24.

DR. IRA COLE has removed from Williamsport to Linden, where he will take over the practice of the late Dr. Mitchell.

DR. CHARLES A. BARNHILL has moved his office from the Hume-Mansur Building to Suite 536-540 in the Bankers Trust Building.

PROFESSOR STANLEY COULTER, dean of Purdue University, will head the annual Christmas seal sale in Indiana this year.

DR. FREDERICK J. FRESHLEY, of Evansville, has been found guilty by the federal court of violating the Harrison narcotic law.

DR. CLEMENS VON PIRQUET, Vienna, has arrived in New York. He will deliver the Stillman course of lectures at Yale University this winter.

A VOCATIONAL training center is to be established at the Irene Byron Hospital at Fort Wayne. Dr. John H. Rhys will have charge of the work.

DURING the year 1920 in the birth registration area of the United States, 1,508,874 births were reported and in the same area 836,154 deaths were reported.

THE Randolph County Medical Society held its meeting in the new hospital at Winchester, November 15. A paper was presented by Dr. Milliken of Ridgeville.

DRS. S. L. MCKINNEY, H. K. STORK, of Huntingburg, and J. P. Salb of Jasper, have been appointed members of the staff at St. Mary's Hospital, Evansville.

THOMAS I. CARRITHERS has donated five thousand dollars to be used in the purchase of a home suitable for nurses of the Methodist Hospital at Princeton, Indiana.

THE Steuben County Medical Society held a meeting November 25. Dr. Eric Crull of the Irene Byron Hospital, Fort Wayne, presented a paper on the "Prevention of Disease".

THE Fourth District Indiana State Nurses' Association held a meeting November 9. Mrs. C. D. Fansler, of the Methodist Hospital, Indianapolis, was elected president.

DR. O. G. BRUBAKER, for seven years a medical missionary in China, has opened an office in North Manchester for the special practice of eye, ear, nose and throat diseases.

A NEW corporation by the name of "The Clinic" has been established at 501 Pine Street, Michigan City, for the purpose of establishing and maintaining a sanitarium and hospital.

THE Tenth District Medical Society held its meeting at Gary, November 10. Papers were presented by Drs. W. A. Shackelton, Charles A. Elliott and Louis J. Pollock, all of Chicago.

THE Wabash County Medical Society held its meeting at Wabash, November 17. Dr. LaSalle presented a paper on "Tonsillectomy" and Dr. More discussed "Incipient Tuberculosis".

THE state tuberculosis hospital at Rockville, Indiana, will be enlarged in order that ex-service men afflicted with tuberculosis may receive care without leaving their home state.

THE Huntington County Medical Society held its regular meeting at Huntington, November 1. Dr. Wallace Grayston read a paper on "Intussusception". Dr. Charles H. Good led the discussion.

THE Benton County Medical Society held its meeting at the home of Dr. W. H. Taylor, November 8, and elected the following officers for 1922: President, O. M. Flack, Boswell; Secretary, J. L. Morehouse, Fowler, Indiana.

DR. B. W. HARRIS, of Uniondale, has located in Gary, Indiana, where he will engage in the practice of medicine as a member of the firm of Craig, Propper & Harris. Dr. Harris will specialize in diseases of children.

THE Hamilton County Medical Society held a meeting at the Houston Hotel, Noblesville, November 8. The principal paper of the evening was presented by Dr. Lafayette Page, of Indianapolis, whose subject was the Riley Memorial.

DR. ANDREW T. CUSTER of Indianapolis announces to the medical profession the establishment of the Custer Rectal Clinic, with offices at 618 Hume-Mansur Building. The Clinic will give medical and surgical treatment to diseases of the rectum, with special attention to the treatment of hemorrhoids and rectal cancer.

THE board of governors of the National Anesthesia Research Society will hold a world's convention of anesthetists in conjunction with their next annual meeting at Columbus, Ohio. Invitations will be sent to the leading anesthetists in London, Paris, Vienna, Buenos Aires, Sydney and other world centers of importance.

THE Ohio Valley Medical Association held its annual convention at Evansville, November 17, and the following officers were elected: President, Dr. L. W. Bremerman, Chicago; first vice-president, Dr. L. L. Solomon, Louisville; secretary-treasurer, Dr. Benjamin F. Floyd, Evansville. The next convention will be held in Evansville.

THE Third District Medical Society held its meeting October 12, at Salem. The following papers were presented: "Occipito Posterior Position in Obstetrics," by Dr. Wm. Green, of Pekin; "The Management of Chronic Valvular Diseases of the Heart," by Dr. Wm. Jenkins, of Louisville; and "The Management of Empyema," by Dr. H. B. Shacklett, of New Albany.

THE Department of Commerce announces that the Census Bureau's annual report on mortality statistics shows 1,142,578 deaths as having occurred in 1920 within the death registration area of continental United States, representing a death rate of 13.1 per 1,000 population as compared with 12.9 in 1919, which was the lowest rate recorded in any year since the registration area was established in 1900.

THE Indiana State Board of Health has instituted a new division of the Board known as the Housing Division. Tenement house surveys will be made in the large cities as rapidly as possible and the exact conditions reported. All plans and specifications made by architects for hotels, lodging houses and tenements must be submitted to the State Board of Health for approval.

DURING November the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: G. W. Carnrick Co., Amylzyme Capsules. Merck & Co., Bromipin 10 percent, Iodipin 10 percent. Tablets. Powers-Weightman-Rosengarten Co., Theobromine-P. W. R. Schering & Glatz, Xeroform-S. and G. E. R. Squibb & Sons, Diphtheria Immunity Test (Schick Test)-Squibb, Diphtheria Toxin-Antitoxin Mixture-Squibb.

DR. DAVID I. MACHT, of Johns Hopkins University, has been awarded the third annual grant from the research fund of the American Pharmaceutical Association for his researches in connection with new antispasmodics. Dr. Macht has found that the benzyl derivatives have all of the sedative effects of the opiates without the objectionable influence of opiates and without an unfavorable reaction after their use. Dr. Macht will continue the investigations of other drugs having a sedative action.

THE mid-winter meeting of the Indiana Academy of Ophthalmology and Otolaryngology will be held at the Claypool Hotel, Indianapolis, all day Wednesday, January 18, 1922. The forenoon meeting will be called at nine o'clock in Parlor B, and the program consists of case reports, new instruments, etc. The afternoon program consists of papers, and the evening includes a banquet and an address. The complete program appears under Society Proceedings in this issue of THE JOURNAL.

THE St. Joseph County Medical Society held its thirty-sixth annual meeting in South Bend, November 16. The program included "Evolution of Symptoms in Diagnosis" by Albert E. Sterne, Indianapolis; "Reflex Abdominal Disorders" by Arthur E. Elliott, Chicago; "Operations on the Gasserian Ganglion with Report of Cases" by John F. Barnhill, Indianapolis; "Conservation of the Patient" by Fredrick G. Dyes, Chicago; and in the evening Dean Stanley Coulter of Purdue University delivered an address on "The Physician and the Public".

THE following resolutions were unanimously adopted at the Mid-Western Association of Anesthetists' meeting held in Kansas City, Mo., October 25:

"WHEREAS, The middle western states are being circularized with false and misleading statements regarding the general practice of anesthesia and particularly the use of nitrous-oxid oxygen, and

"WHEREAS, The Mid-Western Association of Anesthetists is formed for the study and promotion of truth as it relates to the specialty of anesthesia in medicine, now therefore

"BE IT RESOLVED, That this society, in convention assembled, condemns the statements and the actions of Dr. J. F. Baldwin of Columbus, Ohio, in his utter disregard for truth and official records of recognized institutions as these relate to the practice of anesthesia and his efforts to discredit scientific advance by the unethical practice of disseminating false and misleading statements among medical, dental and hospital authorities throughout the United States."

INDIANA University is continuing this year the health education campaign undertaken last spring at the instance of the State Department of Public Instruction, with the primary purpose of interesting people of the state in the employment of public health nurses, and with the additional aim of reaching high school girls, women's organizations, and the general community in such a way as to encourage recognition of the importance of increasing the number of young women being trained for nursing service.

Miss Grace Pitt and Miss Mabel Loveless, registered graduate nurses from the Indiana University School for Nurses, are carrying on the field work, which will take them into practically every county in the state during the next seven months. Mrs. Ethel P. Clarke, director of the Indiana University School of Nursing, has outlined the work of the visiting nurses, while the arrangement of the itinerary is in the hands of the Indiana University Extension Division at Bloomington.

By means of conferences, demonstrations of nursing procedure, exhibits on the care of children, and moving pictures, the nurses strive to make their work of practical value to the communities visited. A program of three days is scheduled for each community, the first of which is devoted to setting up the exhibits and explaining them to individuals and groups. The morning of the second day is taken up with lectures, demonstrations and conferences with high school girls. The work of the public health nurse in the care of babies, in the examination of school children, and in nursing procedure which has special interest for the particular community visited is explained during the afternoon of the second day. The evening program consists of a lecture on community health problems. The third day is taken up with informal conferences by appointment or otherwise with girls as to the nursing profession, with mothers and teachers on the care of children, and with other persons who desire assistance. The visiting nurses carry with them four reels of motion pictures, one reel showing the instructional work given in training schools for nurses, one reel on the uses and methods of handling milk, and two reels entitled "An Equal Chance," which demonstrate the various ways in which children suffering with disease and injury may be brought to normal life.

Last spring the field nurses covered thirty-seven counties of the state, twenty-three of which had no public health nurse, and one of which had no registered graduate nurse in any branch of work. More than 8,500 high school girls attended talks on the preparation of foods and on nursing as a profession, while more than 1,700 mothers and teachers had personal interviews with the nurses on the care of children.

Among the interesting experiences which show the practical value of the health crusade was that of the nurses at Oakland City, where they found a ten-year-old daughter of foreign parents, almost blind. The child attended a lecture by the nurses and after hearing something of what could be done in cases of threatened loss of sight, ran home and brought her mother to the nurses. The interview with them developed the fact that the ignorant mother looked upon the case as entirely hopeless, but the nurses took up the matter with experts at the State School for the Blind, with good prospects for complete restoration of the child's sight.

Among the humorous incidents of their crusade last year, the nurses tell the story of a small boy at Anderson who, after hearing a health talk for children, called up Mrs. Ella Bagot Kehrer, prominent state charity worker, who was serving as chairman of the meetings, and asked her if his ears belonged to his face or to his neck. He explained that he hoped they belonged to his neck, for if they belonged to his face he would have to wash them three times a day instead of once a day if they belonged to his neck.

Last year the visiting nurses found twenty counties calling for public health nurses, without being able to obtain them, and in Ohio county, the smallest in the state, a fund of $1,500 had been placed in the bank to be used for the services of a public health nurse as soon as one could be found.

The nurses carry with them literature on the proposed new Riley Memorial Hospital for Children at Indianapolis and are calling attention to the fact that the hospital, with its heavy staff of nurses, will materially increase the demand for nurses in this state. More than 10,000 children of Indiana are estimated to be in need of hospital attention and this fact is emphasized by the field workers in Indiana's newest health crusade.

CORRESPONDENCE

CONCERNING TARIFF ON CHEMICALS

Indianapolis, Indian., Nov. 15, 1921.

EDITOR JOURNAL INDIANA STATE MEDICAL ASSOCIATION:

Dr. J. N. Hurty recently delivered an address on "The Organic Chemical Industry" at a meeting of about 100 persons in Indianapolis under the auspices of the Indianapolis Branch, American Pharmaceutical Association. Following this address and more than an hour's discussion, the meeting unanimously adopted a resolution asking Indiana's Congressmen and Senators to vote for a continuance of the present embargo on the importation of organic chemicals—medicinal, dye, photographic, etc.

A year or two ago the discussion about an embargo on organic chemicals centered around dyes. As this subject has received consideration it has been shown to extend far beyond this one class of organic chemicals: medicinal chemicals are just as seriously concerned as are artificial dyestuffs.

For example, salicylic acid and its compounds and derivatives, such as acetylsalicylic acid, salol, sodium salicylate, etc., are the most largely used group of medicinal chemicals. So closely are these items allied with artificial dyestuffs that the primary market prices on salicylic acid are given under the classification "Dyestuffs, etc.," in trade reports such as are published weekly in the *Oil Paint and Drug Reporter*. Purified medicinal supplies are not primarily produced as articles of medicines but are drawn from acid produced primarily as an intermediate for artificial dyestuffs. The market price for medicinal supplies is very closely tied to the dyestuffs market.

In a practical way there has been an embargo due to the war for more than four years. In quantities of several hundred pounds on yearly contracts the primary market price on sodium salicylate has been approximately as follows:

1909,	36c	1914,	60c	1915,	$2.05	1916,	$2.30
1917,	87c	1918,	92c	1919,	.50	1920,	.60
1921,	28c						

Practically the embargo is still in operation and this reduction does not give any reason to the consumer to fear that a continuance of the embargo will create a monopoly that will overcharge for its products. This reduction during the past year has been passed along to the purchaser of medicinal preparations of salicylates.

Other medicinal substances closely bound to dyestuffs and like salicylic acid quoted in the dyestuff market report are phenol, cresol, resorcin, acetanilid, phenacetin, all the benzyl derivatives and a host of other important but less largely used articles.

Many chemicals produced originally only as dyes have become valuable as therapeutically active substances. Members of the fluorescin, rosaniline, eosine, and flavine groups have such dual importance. The stains used in bacteriology and in tissue work were first produced commercially as dyes.

Physicians have ample reason to concern themselves with the organic chemical industry and the support which we give it as a nation.

This support can with certainty take no other form than an embargo. Even the enemies of an American organic chemical industry are willing to concede that it should have whatever protection may come from a tariff. But a tariff however high is deceptive. Highly purified naphthaline under present custom regulations is covered by an almost prohibitive tariff, but naphthaline of a lower melting point and hence assumed to be less pure is almost free from tariff. Highly purified naphthaline sprayed with water (a small percentage only) takes on a lower melting point and hence evades the tariff. Such uncertainties as this destroy the usefulness of any protective tariff schedule.

Only an embargo for not less than five years to come will bring to America the certainty of an organic chemical industry suitable for her needs. Each member of the medical profession in Indiana may well declare himself on this subject to his Congressmen and Senators in Washington.

Yours truly,

A. D. THORBURN.

CALCREOSE

CALCREOSE (calcium creosote) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has all the pharmacological activity of creosote but has no untoward effects on the stomach; therefore it may be taken in comparatively large doses for long periods of time.

In the treatment of acute inflammations of the respiratory tract and infections of the gastro-intestinal tract CALCREOSE has been used with good success.

CALCREOSE can be given in comparatively large doses for long periods of time without any objection on the part of the patient.

Write for samples and literature.

BACTERIA RECOVERED POSTMORTEM WITH SPECIAL REFERENCE TO SELECTIVE LOCALIZATION AND FOCAL INFECTION

PRELIMINARY REPORT*

ARLIE R. BARNES, M.D.
FELLOW IN MEDICINE,
THE MAYO FOUNDATION

and

ALFRED S. GIORDANO, M.D.
FELLOW IN PATHOLOGY, THE MAYO FOUNDATION,
FIRST ASSISTANT IN SECTION ON PATHOLOGIC ANATOMY, THE MAYO CLINIC,
ROCHESTER, MINNESOTA

Hippocrates mentioned that abscess of the ear and necrosis of the jaw may be due to infected teeth. More than one hundred years ago Benjamin Rush advanced the opinion that decayed teeth "were the unsuspected cause of general diseases", and reported a case of rheumatism of the hip-joint cured by the extraction of a decayed tooth. The importance of the relation of foci of infection to general diseases is conveyed by the fact that Evans cites thirty-eight acute and eleven chronic diseases which today are considered focal in origin.

Meisser and Rosenow, working in the Mayo Foundation, have reproduced perfectly in dogs the conditions of focal infection as they probably occur in man. They removed in a sterile manner the pulps from two teeth of each of four dogs and infected the pulp chambers with bacteria from the tonsils of a patient with focal nephritis. The pulp chambers were then sealed with amalgam and the animals allowed to live three months. These organisms localized in the kidneys of each of the four dogs, producing focal and diffuse lesions, the varying ages of which indicated that the kidneys had sustained a series of successive or continuous invasions by bacteria.

Experimental evidence to explain the probable *modus operandi* of focal infection has been accumulating. Forssner, using streptococci that did not show specific pathogenicity for the kidney, cultured them in kidney tissue and kidney extract, after which they developed special affinity for kidney tissue when injected intravenously into animals. Rosenow, while studying the transmutations within the streptococcus-pneumococcus groups, noted that as avirulent strains were passed through animals they acquired increasing virulence and exhibited a selective affinity for certain tissues. Thus it occurred to him that a similar mechanism might obtain in diseases focal in origin. For example, only a streptococcus low in the scale of virulence was found capable of producing chronic infectious endocarditis, while this same organism with its virulence increased by repeated subculture was capable of producing malignant endocarditis!

What determines the specific invasive powers of an organism is not clear. Evans points out that the *Treponema pallidum* may invade the uninjured mucous membrane of the lip and that the gonococcus may invade the mucous membrane of the conjunctivæ, while these structures are peculiarly resistant to invasion by other organisms, indicating that certain organisms have specific invasive powers. Evans believes that tissues with intrinsically poor blood supply are favorable to localization since the low supply of food and oxygen allows bacteria of low virulence but highly sensitive to oxygen to obtain a foothold. Rosenow believes that in regions of low blood supply a gradation of available oxygen affords optimum conditions for the growth of bacteria.

Dissemination of bacteria from foci of infection occurs by way of the lymphatics or the blood stream. Experimental evidence indicates that the latter is the most frequent avenue of infection and that the invasion is embolic in character!

In a bacteriologic study of 213 cases at necropsy we came to the conclusion that bacteria recovered postmortem have definite intravital significance and if the invasion occurs after death it very rarely, at least, occurs within the period after death covered by our studies. We

*Presented before the Medical Section of the Indiana State Medical Association, Indianapolis, September, 1921.

decided to determine whether these organisms possessed the same power of specific localization as those recovered before death. Certain teeth incriminated by ante mortem examination were available for careful study and were cultured. The organisms recovered were injected into experimental animals. In certain other cases the selective action of bacteria not recovered from foci was tested. The morbid conditions studied included nephritis, gastric ulcer, tuberculous meningitis, and peritonitis. Case 342540 is illustrative of the results.

Case 342540. Mr. V. S., aged sixty-eight years, came to the Clinic complaining of involuntary and frequent urination. Urinary symptoms had developed five years before, and symptoms of duodenal ulcer had been present intermittently for twenty years. Cystostomy was performed as a diagnostic measure; epithelioma of the bladder was found and a hopeless prognosis given. The anatomic diagnosis at necropsy included a perforated gastric ulcer, duodenal ulcer, old healed duodenal ulcer, marked dental caries and sepsis, suppurative cysto-ureteropyelonephritis, with focal abscesses of both kidneys, and epithelioma of the bladder.

Six teeth were removed aseptically, around two of which there was periapical infection and around two granulomata. From the apices of the teeth staphylococci and streptococci were cultered. Diplostreptococci were found in the smear and culture from the granulomatous material. From the kidney the culture yielded chiefly colon bacilli and a few chains of streptococci. Rabbits were injected with glucose-brain-broth cultures of infected tooth apices, others with a normal saline suspension of periapical pus, and still others with a glucose-brain-broth culture of the patient's kidney. Table 1 shows the results obtained.

Besides the results presented in Table 1 injections into four other animals were made. Streptococci and staphylococci isolated from the apex of a tooth in Case 342540 when injected intravenously in Rabbits 52 and 53 produced only gastric ulcers. Colon bacilli and a few streptococci isolated from the patient's kidney when injected intravenously into Rabbits 56 and 57 proved to be very toxic and no localization was exhibited.

Attention is called to the fact that when the streptococcus was isolated from the stomach of Rabbit 54 and injected alone, gastric lesions resulted in two of three animals. When the staphylococcus was injected alone it tended to localize in the kidney and heart, producing focal

abscesses, a rather characteristic behavior of this organism according to our observation when it is injected intravenously. Indeed, our observations have led us to believe that the staphylococcus does not tend to localize in the sense that the members of the streptococcus-pneumococcus group do. The staphylococcus always tends to focalize in certain structures, particularly the heart and kidney, but this occurs regardless of the source from which the organism has been isolated. This behavior of the staphylococcus is explicable on the basis of well known bacteriologic and anatomic considerations and ought not be spoken of as selective localization. This explanation does not mean that in this case the staphylococci recovered from the teeth could not be related to the renal lesions in the patient.

In our experiments in this case attention was directed to the teeth as a focus of renal infection, but we found that gastric ulcers were quite as frequently produced as renal lesions. This is significant, since gastric ulcers were found in the patient, and illustrates the value of knowing in a given case all of the lesions which can be focal in origin. It is possible that in the ante mortem study of lesions focal in origin, results which at times appear irrelevant actually have their counterpart in an unsuspected lesion of the patient.

The results of animal injections in five other cases of predominant renal lesions are tabulated in Table 2.

Reference may again be made to the gastric ulcers resulting in animals injected with organisms recovered from infected teeth in Case 342546 (Table 1). Two other cases of gastric ulcer were studied in which the teeth were definitely diseased. Organisms recovered from these foci when injected intravenously into rabbits produced gastric ulcers in three of four animals in one case and in each of two animals in the other case.

Two cases of tuberculous meningitis were studied in which there was an added pyogenic infection. From the brain in these cases diplostreptococci were cultured. These organisms were demonstrated in the brain and cord by the Gram-Weigert method of staining. When they were injected intravenously in Rabbits 80 and 82 and subdurally in Rabbits 81, 83, and 85 they exhibited selective localizing power in the central nervous system of these animals.

In control experiments we have made similar intravenous and intradural injections of pneumococci, indifferent streptococci, and hemolytic streptococci in approximately the same dosage

as used in the foregoing experiments. In these control animals we have failed to produce any localization in the central nervous system. Thus it appears that the organisms in the two cases above possessed a potential affinity for the central nervous system, and this affinity was demonstrable both by intravenous and intradural injection.

Three cases of peritonitis, studied bacteriologically, had occurred without any preceding abdominal operation and at necropsy no intra-abdominal source of peritoneal infection could be ascertained after a most careful search. These cases fall into the class of cases of peritonitis designated as primary by Flexner. In two of the cases, cultures revealed septicemia. This finding suggests that in exceptional cases peritonitis may be primarily septicemia which localizes in the peritoneal cavity. Case 335984 is illustrative.

Case 335984. Mrs. H. R., aged fifty years, was admitted to the Clinic complaining of abdominal pain. The onset had been sudden and characterized by pain and tenderness in the right lower abdomen. One day later, vomiting had begun and the pain had shifted to the upper abdomen. The third day the abdomen had become enlarged.

The patient's condition was considered inoperable on admission. Death occurred two days after admission.

At necropsy a diagnosis was made of primary diffuse purulent peritonitis, early bilateral seropurulent pleuritis, acute diffuse nephritis, and pyorrhea alveolaris. Cultures of the blood, spleen, peritoneum, apex socket, and canal pulp of a tooth all yielded hemolytic streptococci.

Mouse 1 was injected intraperitoneally with 0.5 c.c. of the culture from the peritoneal fluid of the patient. The animal died on the third day. In its abdominal cavity was a small amount of bloody fluid, and the intestines were covered by a fine fibrinous exudate. There were no other evident lesions in the body. Cultures of the blood, spleen, and peritoneal fluid yielded hemolytic streptococci. Similar results were obtained in three guinea pigs and one mouse.

Rabbit 23 was injected intravenously with 5 c.c. of a glucose-brain-broth culture from the tooth pulp of the patient. On the sixth day the animal was apparently ill and did not wish to move, and its abdominal muscles were very rigid. It was chloroformed. At necropsy the peritoneum was lusterless and the peritoneal cavity contained a small amount of cloudy fluid. The abdominal organs were covered with a thin sticky exudate. On gross examination no lesions were found elsewhere in the body. The peritoneal fluid, spleen, and blood yielded pure cultures of hemolytic streptococci.

This experiment suggests the possibility that organisms harbored in the infected tooth may have acquired sufficient virulence or have met with such a decrease in resistance that they were able to cause septicemia and peritonitis. It must also be considered that the organisms recovered from the infected tooth may have been a part of the general septicemic infection. These results may be significant with reference to certain cases of peritonitis following operative procedures in the abdomen and suggest that under certain conditions of disturbed resistance organisms contained in foci may acquire general invasive power, and a patient in such a condition would be a poor surgical risk.

Necropsies were performed carefully on all of these animals. Evidence of pathologic change was judged by gross findings, and organs grossly involved were sectioned for microscopic study. It would be obviously desirable to make a microscopic study of all the tissues in the body, but such a procedure assumes almost forbidding proportions, and in large measure the gross lesions will give a good estimate of the regions that are chiefly involved. When we speak of certain lesions being the only lesions found, we mean that grossly no other pathologic changes were evident.

Discussion. The arbiter in questions of focal infection must be the internist and not the specialist. The specialist may render an opinion as to the local condition of the foci. Only the man acquainted with the patient's general condition can safely recommend the removal of foci, and he will be due for disappointment if his diagnostic acumen is not exercised to its fullest extent. It is obviously useless, for example, to expect the removal of foci to ameliorate conditions if the pains are ascribable to neuritis due to pernicious anemia, or to root pains due to an early neoplasm, or Pott's disease. Even then recommendations are of value only if the specialist and internist control their judgment by carefully following their cases and supplement their knowledge whenever possible by bacteriologic studies and animal experimentation. Another source of disappointment lies in the fact that often we can eliminate foci only after the insult has been long repeated and the damage done is irreparable or self perpetuating. It is the present belief that in long standing cases secondary focalization, for example, in a joint, may be established which obviously may not be eliminated by the removal of the original focus! It is evident, therefore, that early diagnosis and early location of foci is highly desirable in order to secure the most satisfactory results.

SUMMARY

1. In our experimental work bacteria recovered from various locations at necropsy including foci of infection exhibited selective localizing power in animals.

2. This selective localizing power has been demonstrated in eleven of thirteen morbid conditions, comprising cases of nephritis, gastric ulcer, encephalitis, and primary peritonitis.

3. Our evidence illustrates a valuable method of testing the ability to diagnose certain foci as related to disease processes.

4. It is emphasized that the specialist may render an opinion concerning the pathology in a suspected focus of infection, but conclusions as to its importance and treatment are to be left in the hands of the internist.

5. Careful control of the clinician's and specialist's judgment concerning foci by following up their cases and, if possible, supplementing their knowledge by bacteriologic study and animal experimentation will endow their opinions with the greatest value.

6. Early discoveries of foci and their removal yield the most satisfactory results. Long continued insult may result in irreparable damage or a self perpetuating process in a given structure. In such cases a guarded prognosis must be given, although the patient should be given the benefit of a possible cure.

DISCUSSION

DR. VIRGIL MOON (Indianapolis): It happened to be my good fortune to be working in the laboratory of Dr. E. C. Rosenow at the time he was collecting the evidence which led to his giving out to the medical profession this evidence of focal infection. I saw him excise from the deltoid muscles of a patient who was acutely ill with muscular rheumatism a bit of muscular tissue. I made sections of that tissue myself and demonstrated in it streptococci. Dr. Rosenow cultured a bit of the tissue and obtained a pure culture of streptococci. These were immediately injected into animals—rabbits, guinea pigs and dogs; and not only did that organism localize in the muscles of those animals, but it localized in the shoulder muscles of those animals, giving a striking example of the selective action of the organisms.

I saw Dr. Rosenow isolate from the stomach mucosa streptococci and those cultures injected immediately into animals produced, as Dr. Barnes described, ulcers of the stomach. Not joint lesions, not muscular lesions, no localization in the gall bladder or the kidney or elsewhere, but in the stomach mucosa.

Again I saw him cultivate organisms from the gall bladder in cases of cholelithiasis, which organism when injected into animals immediately produced inflammation of the gall bladder. I have seen such performances, have seen the organism at the time it was first isolated, and then have had the experimenter show these lesions at points corresponding to those from which the same bacteria occurred in the patient, and not elsewhere. Such experiences cannot help but convince us of the selective affinity of these organisms under certain conditions. You, as internists with experience in various kinds of infection, have no doubt seen your patients with a diseased tooth or tonsil, with definite evidence of infection elsewhere in the patient, and you have no doubt seen those foci subside—not always, upon the removal of the original focus of infection. That should be to our minds evidence of the fact that there is something in selective localization, a selective tendency on the part of the organism to infect certain tissues. It is a striking fact that when these organisms have first been removed they give evidence of this selective localization, but after they have been cultured in the laboratory for a time they seem to lose this selective localization tendency and acquire an affinity for the joints and muscles, with rheumatism, and we get the affections of the joints and the muscles from these bacteria which have lost their particular selective affinity for the kidney, the gall bladder, the stomach mucosa, or other forms from which the organism was originally cultivated.

DR. GEORGE W. MCCASKEY (Fort Wayne): I have been from the outset convinced of the value of Rosenow's conclusions in regard to the elective affinity of bacteria for different organs and structures. In fact, his work has been so scientific, and his facts so firmly established, that I believe we must either repudiate his facts, or in a general way accept his conclusions.

It was a brilliant conception to find the focal infections postmortem, collate them with pathology, and proceed to establish their etiologic relationship by animal experimentation, and this has been done in a most convincing manner. The complete control of all of the conditions, with the possible exception of the time elapsing between death and autopsy, has made it possible

to lay the foundations for definite conclusions, and the work subsequently to be done by the internist, with great scientific accuracy.

A clinician cannot, of course, work under such conditions, but it seems quite possible, and therefore assumes somewhat the character of an obligation, at least in many cases, using every possible check, to work the problem out clinically. Everyone of experience recognizes the tremendous difficulties which we encounter clinically in "running down" a focal infection, which we feel certain exists somewhere. The teeth and tonsils are, of course, the chief points of attack, and too frequently the only ones, as peri-nasal sinuses, gall bladder, appendix, prostate gland, etc., etc., may be guilty.

In regard to the teeth, the difficulties of interpretation are very great. While it looks on the surface like a dental question, the conclusion is forcing itself on my mind that the clinician must ultimately make his own decision. One dentist will say, "take them out", and another, with the same evidence, will say they are harmless; which leaves the patient and the clinician "between the devil and the deep, deep sea".

Having found the focus, or abscessed tooth or tonsil, we cannot say at once that it is the cause of the pathology, any more than we can say that a positive Wassermann reaction points us to the main etiology in any given syndrome presented to us and associated with a positive Wassermann reaction. This work of Rosenow and his collaborators seems to point the way to the solution of this problem in many cases, and Dr. Barnes emphatically tells us that the responsibility is now up to the internist. This is certainly adding a few more straws to the load which we were carrying, but we will accept the responsibility with the best possible grace.

DR. HENRY E. ALBURGER (Indianapolis): I think we are ready to assume that the organisms are specific, that they have special tissues which they invade, and the point we internists are up against is a vexed one because we are dependent, I feel, upon the character of the work done by the men who ultimately remove the focus of infection. If you send a man to a dentist you are dependent upon the opinion of that dentist. He may be an up-to-date man or a very un-up-to-date man. I have had dentists refuse to take out teeth which I knew were infected, and were afterward proven to be so. I have seen many cases in which teeth were improperly removed—simply pulled out without removing the infection at the root. I have known cases in which we were able to demonstrate, fifteen years after extraction, that there was a granuloma at the apex which was still the source of local infection. I feel, therefore, that we are still responsible after sending patients to the dentists and nose and throat men, and that we are responsible for the work done by them on our patients. We cannot safely send a patient with focal infection to just any man either in nose or throat work or in dentistry.

DR. FRANK WYNN (Indianapolis): With the practitioner there is the confusion of mind as to where the focus of infection is that gives rise to the neuritis or rheumatism. We look at the teeth, the tonsils, the gall bladder, and everywhere we can think of and then say, "Where is it?" The tendency of the time is to blame the thing that is easy to find. That is, we look in the throat and if the tonsil shows any suspicion of disease how easy it is to say that it must come out. Or, if there is any reason at all to suspect the teeth are responsible, and especially if some over-enthusiastic radiologist makes a picture which arouses hope, here seems an easy way to get rid of the trouble and we say, "Take out the teeth." I think we are too drastic. My point is this, if Dr. Barnes can, in the post-mortem room, find the connection between—let us say the organisms at the root of an offending tooth and a gastric ulcer, then why should not every operating man make similar demonstrations? How many men extracting teeth are carefully studying the sockets from which they were removed? How many are making cultures and trying to determine whether there is any connection between the trouble complained of and the bad teeth? How many are making cultures from the tonsils when they are removed to see if there is a definite relationship between rheumatism and the tonsil removed?

DR. ROBERT V. HOFFMAN (South Bend): In regard to the nose and throat men, I know one man who has consistently taken cultures of every tonsil he has removed during the past two years. Almost without exception they have shown streptococcus hemolyticus, sometimes staphylococcus, but nearly always the streptococcus hemolyticus. He has not injected animals but he does make the cultures in practically every case. He has been unable to derive any facts of practical value from his findings.

DR. ARLIE R. BARNES (Rochester, Minnesota—closing): In answer to Dr. McCaskey's question as to how long the organisms were cultured after death, our postmortems were made about six hours after death, on the average.

I think there is a little hope for the profession on the standpoint of passing upon foci of infection, especially of the teeth, and I think the Mayo clinic is rendering much service in standardizing these criteria. They are culturing all these teeth routinely to decide whether they are infected and whether their radiological judgment is confirmed or discounted. I think many

teeth are pulled and a focus of infection left behind, as Dr. Alburger said, and I think the time is coming when the teeth will be removed surgically. The Mayo clinic is doing the external alveolectomy, chiseling out the bone, lifting the tooth out carefully, cleaning out the socket and sewing up the gum. The healing is perfect and they get very excellent results.

We find that if we carry the cultivation through more than one artificial media we get into trouble, unless we cultivate on a special media by which we can keep up the virulence of the culture a little longer. On blood agar plates the selective localizing power is lost very quickly.

I wish to thank the gentlemen for elaborating this paper in their discussion, and I consider it a great honor to have had the opportunity of addressing this body.

TRACHOMA OR FOLLICULOSIS AMONG SCHOOL CHILDREN*

J. A. STUCKY, M.D.
LEXINGTON, KENTUCKY

It is an interesting coincidence that ten years ago today in this city at the meeting of the American Academy of Ophthalmology and Otolaryngology, I presented an informal report on "Trachoma and Ophthalmia in the Kentucky Mountains". My report was simply a "heart-to-heart talk" with the leading ophthalmologists regarding the greatest problem I had ever confronted. It was in reality an "S. O. S." call for help. My curiosity, not unmixed with ambitious conceit, had led me into the mountains to ascertain where the large number of cases of trachoma that I saw were coming from, and I was determined to ascertain the cause and to remove it.

As a result of my report, the House of Delegates of the A. M. A. notified the United States Bureau of Public Health in Washington to get in touch with the State Board of Health of Kentucky and ascertain if my report at this meeting was not an exaggeration. As a result of this, a few months later, at the request of the State Board of Health of Kentucky, Dr. Jno. McMullen, one of the expert diagnosticians in trachoma, representing the U. S. B. P. H., accompanied me on one of my Mountain Clinics and reported to the Board in Washington and to the State Board of Health in Kentucky that he found the percentage of the cases among the inhabitants in "the heart of the hills of Kentucky" was more than twice what I had estimated. At the earnest solicitation of our State Board of Health Dr. McMullen was ordered to remain in the Kentucky Mountains, with sufficient help to arrest or eradicate the disease. Five hospitals were equipped with surgeons and nurses at each, and several thousand cases of the disease were treated under the supervision of Dr. McMullen. The result of this has been a very decided decrease in the activity of this disease. Many have been relieved of their suffering and their impaired vision restored. Thus you see that in this city a decade ago, a great work for humanity was started, and I am delighted to report the great progress we have made in the treatment of the disease. We have not only been able to relieve but to arrest its ravages, though I am humiliated to report that the specific etiological factor in its production has not been ascertained, and I am hoping that today, at this meeting, we may receive some suggestion and cooperation from you that will enable me to report in another ten years or less that this etiological factor has been isolated, the disease controlled, and that what has for so long a time been a reproach to ophthalmology has been removed.

As a result of the publicity given this work in Kentucky, through the magazines, medical journals and bulletins published by the U. S. B. P. H., the whole civilized and scientific world, including both Europe and America, speak of the mountains of Kentucky and Eastern Tennessee as being one of the hotbeds and breeding places of what the government has pronounced "a communicable and destructive disease of the eye."

As near neighbors of Kentucky, with whom we have much in common, I feel that I have the right to come to you with a continuance of my heart-to-heart talk of ten years ago, asking and expecting helpful suggestions from you that will lead to a concerted, concentrated and persistent effort on the part of the medical profession, philanthropists and sociologists to spare no effort or expense to ascertain and isolate the specific etiologic factor in the cause of trachoma.

As I stated ten years ago, I repeat today, I am not certain whether it is of bacteriological origin, whether it is a fly-borne, insect-borne, house disease, or whether it is due to a specific micro-organism, but I am convinced that it is not as actively infectious as I thought it then, and is less amenable to permanent eradication; and I am more and more convinced that it requires for its solution in addition to medical and surgical treatment more sanitary and hygienic living. Wherever high-grade schools exist, with community nurses and the laws of sanitation and hygiene are observed, the ravages of this disease have diminished.

Within the past year much interest and discussion have been caused among ophthalmologists, boards of health and school boards, especially of the South, regarding the increase of this disease in insidious form in the public

*Read before the Section on Ophthalmology and Otolaryngology of the Indiana State Medical Association, Indianapolis Session, September, 1921.

schools. This interest and discussion have extended to the far West, especially where the disease has been found among the Indians in one or two places, and considerable heated discussion has taken place over the difference in diagnosis between conjunctival folliculosis and trachoma. Objection has been raised in some localities to the somewhat radical procedure advocated by the public health officials in dealing with suspicious cases. Because of this discussion, led chiefly by Dr. J. W. Jervey, Greenville, South Carolina, a committee was appointed at the meeting of the A. M. A. at New Orleans, Louisiana, in 1920, to go carefully into the subject and report at its next meeting, which was held in Boston this year, the points of differentiation between folliculosis and trachoma, with suggestions as to what should be done. This report, with which you are no doubt thoroughly familiar, was made somewhat at length to the Section on Ophthalmology, and being a member of that committee, I have nothing to add, but will repeat my discussion of Dr. Jervey's paper* before the Louisville and Jefferson County Medical Society, May 2, 1921.

The greatest problem confronting the country today is how to handle the trachoma situation. The United States Bureau of Public Health has accomplished much good work, and so far as I am able to judge the progress of the disease in the mountains has been arrested, its ravages have been mitigated, but whether many cures actually have been effected I have yet to decide. I confess that I do not know when trachoma is permanently cured.

The citation of a few (out of a large number) concrete cases may be interesting: I operated upon a child (female) for trachoma nearly twenty years ago. The disease recurred from time to time and she was subjected to several subsequent operations. Dr. McMullen, U. S. B. P. H., an expert in this line of work, operated on her once; later one of his assistants operated her. She is now about thirty years of age and came to me a few days ago with another "flare up" of her trachoma. Inspection shows the conjunctiva brawny, smooth, many cicatrices are present, and characteristic new trachoma bodies are visible, with entropian both upper and lower lids.

I recall a prominent Methodist minister upon whom I operated fifteen years ago. I thought he was cured and told him so. Last winter he returned with the most severe and intractable "flare up" that I have had to deal with in many years. I consider trachoma one of the most mysterious and treacherous of diseases.

There is just now a great interest among medical men of the United States about the differential diagnosis between folliculosis and trachoma. And, candidly, notwithstanding our large experience with the disease in the mountains of Kentucky and Tennessee, I do not believe a differential diagnosis can always be made in the early stages.

A few years ago twelve or fourteen cases of trachoma were reported to me by the Medical Inspector of Schools in Lexington. Upon examination of these cases I confirmed the diagnosis and the children were excluded from school. They all had evidence of acute trachomatous folliculosis with discharge and photophobia. I ordered these children to the hospital for operation, but not one of them reported. I then appealed to the Board of Health without any immediate results, and in the meantime the inflammation and discharge subsided, under care of the district nurse who was giving the treatment I had ordered. The Health Board asked me to examine the children again a month later, which I did, and at that time the disease did not look so much like trachoma but more like folliculosis, so I concluded that I must have been mistaken in my original diagnosis. To make a long story short, these twelve or fourteen children, and thirty or forty other border line cases, have been kept under close observation for four years. They showed marked improvement after removal of their tonsils and adenoids, and were permitted to return to school. It is evident that they did not have trachoma.

My ideas about the diagnosis and treatment of trachoma have undergone material changes during the last few years. In true trachoma I believe in being radical, so far as treatment is concerned, but we should be certain that we are dealing with true trachoma before resorting to radical measures. I am not sure that I can make a diagnosis of trachoma in the early stages, and we are waiting for somebody to determine definitely the etiology of the disease. We are told in the beginning trachoma looks like ordinary conjunctivitis, but if extensive hypertrophy occurs, if the conjunctiva cannot be stretched, and the blood vessels plainly seen, especially if other members of the family or anybody in the neighborhood with whom the patient comes in contact show conjunctival cicatrices, then I at once convict that patient on circumstantial evidence and treat the case as trachoma.

I have just gone through a long siege in the committee on trachoma appointed by the Section on Ophthalmology of the American Medical Association, with especial reference to differential diagnosis of folliculosis and trachoma, and my views in brief are as follows:

"In my mountain clinics it has been difficult to decide whether a case in the acute stage

*Folliculosis or Trachoma Among School Children—J. W. Jervey, Greenville, S. C.

was trachoma, but if the conjunctiva was thickened and inflamed, and there were other cases of the disease in the family or the neighborhood, the case was regarded as suspicious and treated as trachoma. In the second stage my differential diagnosis between trachoma and follicolosis of the conjunctiva was based on my observation that in simple follicular hypertrophy (that is, adenoid hypertrophy of the sub-epithelial layer of the conjunctiva) the conjunctiva is easily and evenly put on the stretch, the whole membrane being elastic and the blood vessels easily seen. But where the hypertrophy involves the whole body of the conjunctiva (papillary hypertrophy or papillary thickening) then the conjunctiva cannot be stretched and the blood vessels are not visibly outlined. While this is a pathological differentiation, it is applicable in the study of every case. I prefer the term *adenomatous conjunctiva,* inasmuch as it covers the ground whether or not there are inflammatory phenomena present, and does away with the necessity of distinguishing between folliculosis (without inflammation) and follicular conjunctivitis (folliculosis plus inflammation).

Whether trachoma exists in epidemic, pandemic or endemic form in the public schools of the South I do not know, but I am sure it does not in Lexington. I see more of it now in central Kentucky than ten or fifteen years ago, and the majority of the cases come from the type of individuals and surroundings living in the mountains of Kentucky; but I have seen persons with trachoma who were reared in affluence, with perfect sanitary and hygienic surroundings. One was a prominent lawyer, and another the minister to whom reference already has been made.

The disease is undoubtedly conveyed from one person to another by morbid secretion, but whether this contains micro-organisms or some other infective substance we do not know. In my opinion trachoma in the terminal or cicatricial stage is not contagious; it is contagious only in the active stage when there is secretion. My observation has been that pannus is almost pathognomonic of trachoma; in fact, I do not recall having seen a single patient with pannus who did not have trachoma.

Differentiation between trachoma and folliculosis cannot always be made by sight nor even by the microscope, and where we cannot be positive, I believe we should give the patient the benefit of the doubt, and treat the case as suspicious. I do not believe every suspicious case should receive the radical treatment of grattage. To properly do this operation requires surgical skill and judgment.

There are certain phases of the trachoma problem about which we must be careful. Some of the after-effects of trachoma cannot be relieved by any means of which I have knowledge. The following are quotations from several who discussed the question raised in Dr. Jervey's paper on Folliculosis or Trachoma Among School Children:

DR. J. O. CARSON, Bowling Green, Ky.

"I do not believe early cases of trachoma ever will be positively diagnosed until the specific causative factor has been demonstrated by bacteriological and microscopic investigation. Some observers claim to have isolated the causative agent, but their findings lack confirmation. Until the etiology is settled, a positive diagnosis of trachoma cannot be made unless scar tissue is present, and then it is too late to accomplish very much by treatment.

"Epidemics of trachoma occurring in armies is an entirely different matter. Owing to their surroundings soldiers are probably oftener exposed to exciting causes than are civilians, and therefore trachoma is not uncommon. Many cases were observed in the various camps during the war.

"I am aware of instances where folliculosis was treated as trachoma with considerable destruction of tissue and resulting deformity. The operation usually performed for trachoma may seem a simple procedure, but sometimes the patient is in worse condition afterward than before. For that reason I am inclined to treat the patient by simple measures until the nature of the disease is positively determined. It hardly seems necessary to say that patients with trachoma should only be treated by someone who has had experience in that class of work."

DR. JNO. MCMULLEN, U. S. B. P. H.

"If a case is counted as suspicious of trachoma, of smallpox, or of any other communicable disease, if we honestly believe it is suspicious, is it fair to permit the patient to associate with others to determine whether or not they will contract this particular disease? Those of us who have been working in trachoma for a long time and have seen its detrimental and damaging effects upon the eye, believe that the disease has certain potentialities, and that suspicious cases should not be permitted to come in contact with the well. That should be our attitude in regard to all communicable diseases.

"We see cases of trachoma affecting one eye, even progressing to the stage of cicatricial tissue formation, the other eye not being involved. We have often been asked why that is. I do not know, but we realize there is a great deal about immunity that we have yet to learn. The same question might be asked concerning gonorrheal ophthalmia; why do not all men with gonorrhea have ophthalmia, and why do not both eyes become infected? A similar statement might be applied to scarlet fever and many

other diseases; why does not the disease affect every member of the family? When speaking of the cure of trachoma of course I realize that in some instances the disease may recur, but this is no reason why we should not make an effort to cure it.

"In 2,900 cases of trachoma in which our records are known to be complete, though many of them are incomplete, because some of the patients live in remote districts and the end-results cannot be determined until we can again examine them, of the 166 children under five years of age included in the above, 19 had ulcer, 23 impaired vision, 60 had photophobia, 25 had pannus, 3 were blind in one eye and 1 in both eyes. Between five and ten years of age there were 631 cases. I will not take the time to present further statistics except to say that 50 percent of our trachoma patients had photophobia; from 25 to 30 percent had pannus; 10 to 15 percent had ulcers. I have about concluded that blindness may not be the worst result that can happen to a child with trachoma. With deformity of the lids, with damage to the ocular structures, with dwarfing of both body and mind as these children develop, simply because their entire lives are spent in shielding their eyes from the light, their condition is indeed pitiable."

DR. S. G. DABNEY, Louisville, Ky.

"I believe all suspicious cases should be treated as trachoma. They are rare in our community and from what I have read they are elsewhere outside of certain localities. Genuine cases are not always from the mountainous regions. I have seen a good many cases of trachoma from southern Illinois (hence the name 'Little Egypt' some say), a few from Jefferson and other counties in Kentucky. However, the majority of the genuine cases of trachoma I have seen were from the mountains of Kentucky and Tennessee. I have seen a few cases in the school children of Louisville. It hardly seems necessary to state that all cases of genuine trachoma should be operated upon at the proper stage, but often operation fails to cure when at first it seems perfectly satisfactory."

DR. ADOLPH O. PFINGST, Louisville, Ky.

"In trachoma there is a thickening of the mucous membrane between the follicles; in folliculosis the follicles seem higher than in trachoma, but this is more apparent than real, the lymphoid follicles are of the same size in each disease, but owing to the thickening of the conjunctiva in the early stage of trachoma the follicles appear less elevated than in folliculosis in which the conjunctiva is less swollen."

DR. J. W. JERVEY, Greenville, S. C.

"No one can differentiate between folliculosis and trachoma in individual cases; the follicles in the early stages are absolutely indistinguishable; but when there are hundreds of cases of conjunctivitis in children, with no papillary hypertrophy and no cicatricial tissue, pannus nor anything else definitely diagnostic of trachoma after prolonged observation, it may be positively stated that there is no trachoma among such children."

Having given briefly my own views and those of several leading oculists of Kentucky who see many of these cases, also the statistics of the cases seen in Kentucky by the representatives of the U. S. Bureau of Public Health Service, as well as their attitude on the trachoma question—and since the report of the committee appointed to define the differential diagnosis between trachoma and conjunctival folliculosis has been adopted by the Section on Ophthalmology of the A. M. A., what more shall we do? Shall we continue to combat conditions and not causes and to fight symptoms and sequelæ instead of etiology?

I am beginning to think that the contagiousness or communicability of trachoma is on a par with tuberculosis, in that it is not actively contagious but is contracted by long continued or repeated exposure to the infection, and when the same thought and effort shall be given to ascertaining the causative factor of trachoma, as was given to tuberculosis, the problem will be solved, but until then the greatest good to be accomplished will be by the Scientific Medical Man, the Public Health Nurse and the Teachers of Hygiene and Sanitation.

DISCUSSION

DR. E. M. SHANKLIN (Hammond): In my opinion the all-important factor in the management of the trachoma situation, not the individual cases but the whole question, is the education of the oculists. I was disposed a year or so ago to regret the disputes that arose concerning diagnosis, but as I view it now that discussion regarding the differential diagnosis between folliculosis and trachoma has been a veritable godsend.

In our own state I recall a report made by Dr. J. W. Neideger of the United States Public Health Service relative to the trachoma situation in Bartholomew County. It seems that when he first went down there he was advised there was no trachoma in that county. His preliminary inspection of the country schools in two townships, brought to light 38 cases of active, second or third stage trachoma. About that time, less than ten years ago, I made inquiry of several doctors in the more populous communities in Indiana and found the reports varied; some oculists claiming there was no trachoma in their communities while others said

they saw from fifty to seventy-five cases annually. That is not so far in the past as to make me change my statement that the education of the profession is a very important thing if we are to properly approach this very important question.

I like the Doctor's statement relative to the differential diagnosis between folliculosis of the conjunctiva and trachoma, and that in the first stage trachoma is difficult to diagnose. I also liked his differential diagnosis in the second stage relative to the tenseness of the conjunctiva and the appearance of the vessels.

The Doctor speaks of grattage, which has come to be the accepted treatment. As a matter of historical interest I might mention that several years ago I heard of the treatment of trachoma by a non-medical man down in southern Indiana. The treatment was as follows: A little stick of copper sulphate was whittled out one inch in length and about a quarter of an inch in thickness. This was placed in an ounce of 50 percent alcohol with a piece of alum about the size of a quail's egg, and a piece of indigo about the same size. The stick was left in there for 24 hours. The upper lid was then inverted and the stick rubbed twice—no more—across the lid. A large basin of boiling water was then brought out and put on a chair in front of the patient, the patient's head enveloped in a large cloth, and he was forced to sit with his face over that hot water and undergo the steaming process for thirty minutes, or until the pain subsided. That treatment was used every other day for a period of two weeks, and failure, according to the history that goes with the story, was practically unknown.

Dr. W. A. Spurgeon of Muncie sent an emissary down there and got the formula by paying for it, and he tells me that until ten years ago he used that treatment with wonderful results.

DR. BERNARD J. LARKIN (Indianapolis): It is a great pleasure and benefit to hear such an eminent authority as Dr. Stucky attack the trachoma problem and it is regrettable that we have not more men to do such scientific work along these lines.

Trachoma is prevalent in Indianapolis, as was shown by the survey during the year 1916. I do not remember the percentage, but it was high, both children and adults. The conclusion arrived at was that it would be better to concentrate on the children because the adults seemed prone to ignore or antagonize our efforts to relieve. With our follow-up system we feel that we accomplished a great deal.

The greatest difficulty encountered was the lack of cooperation on the part of other oculists. For instance, in one district whenever a supposed case was excluded from school the principal immediately got in touch with an oculist, who would give this child a certificate to return to school. However, the Board of Health finally decided that when a child was excluded from school it should not be permitted to return until the survey thought there was no danger.

Dr. Stucky has thoroughly covered the treatment, and I wish only to emphasize that we always get better results in children. I would urge the members of this Association to give especial attention to them.

DR. ALBERT E. BULSON, JR. (Fort Wayne): To Dr. Stucky belongs the credit of having called our attention to the wide-spread prevalence of trachoma in the mountainous districts of the South. The situation demands not only conscientious and skilled treatment of the unfortunates who are suffering from trachoma, but an earnest effort should be made to discover the etiology of the disease with a view to more effectual prevention.

To my notion the Federal Government should expend more money and more time in an effort to determine the etiology of the disease. It also is a work that could well be taken up by the Rockefeller Foundation which, as you know, is spending much time and money in investigating typhus fever, yellow fever, hookworm and some of the other disastrous diseases.

With the public the feature that deserves more emphasis is the fact that trachoma, like all eye diseases of contagious character, is conveyed by fingers, roller towels, handkerchiefs, etc. Much may be accomplished in the way of preventing eye diseases if children are taught that nearly all communicable eye diseases are conveyed by the fingers and consequently the fingers should not be used to rub the eyes.

So far as the recognition of trachoma is concerned I think Dr. Stucky has hit the nail on the head when he says that neither he nor anybody else always can make a diagnosis of trachoma in its acute stage. I have had considerable experience in the treatment of trachoma and while I am satisfied that I can recognize the disease in the secondary stage yet the acute stages of the disease are uncertain of recognition. There must be a specific cause for the disease, and with its discovery there can be no excuse for not differentiating trachoma from any other condition. I made a diagnosis of trachoma in one of our public institutions, an orphan school for girls, where the disease was fairly acute, but that diagnosis was based upon the fact that the disease developed shortly after the admission of an inmate having sore eyes which from the history and appearance of the condition justified a diagnosis of trachoma. My advice that the affected children be isolated was

not accepted and the disease went through the whole school, resulting in much damage and the necessity for treatment and care for years afterward.

Concerning the question of treatment I want to say that, aside from surgical operations, including grattage and excision of follicles or thickened tissue, I think there is nothing better than sulphate of copper. It is a very painful treatment when the pure stick is employed, but there is no question about its efficaciousness. Many years ago I saw a large number of cases of trachoma in the secondary stage which appeared among the foreign population in our city, and at that time Dr. Prince, of Springfield, Illinois, who happened to visit me about that time, recommended a saturated solution of sulphate of copper in glycerine as a routine application, the solution to be diluted as required in order to offset any reaction not well tolerated by the patient. Personally I am satisfied that a severe reaction is beneficial and shortens the time required for recovery, so I usually give an adult patient a quarter of a grain of morphine, and twenty or thirty minutes later, following local anesthesia of the eye, the pure copper stick, or the saturated solution of copper and glycerine, is applied to the everted lids thoroughly. This is repeated about once a week, and in the intervals between treatments a weaker solution of copper is used by the patient at home. I have seen rather remarkable results from this plan of treatment, and it is especially valuable in those cases where the pannus is well marked. Patients usually are asked in advance whether they will stand for the punishment, and invariably they will submit when they are told that the results justify the discomfort.

Again I wish to reiterate that I think we should bring pressure to bear upon the Federal Government, and even the Rockefeller Foundation in an effort to enlist the cooperation of those agencies in determining the etiologic factor in trachoma. We can and should discover the cause, but it probably means an expenditure of more time and more money than can be devoted to it by any agency outside of that subsidized by the Federal Government or Rockefeller Foundation.

DR. GEORGE F. KEIPER (Lafayette): Every case of trachoma is potential for great harm in inoculating many more people. Some twenty-five years ago at the St. Joseph Orphanage and Manual Training School just outside the limits of the city of Lafayette we had a very severe epidemic of trachoma. When the sister in charge first called me I found four boys with sore eyes; at the next visit I found four more. Then I ordered an inspection of the school and found 95 cases afflicted with trachoma in various stages of the disease. We segregated these boys and did not allow them to come in contact with the other boys, but it was two years before the last case was dismissed as cured. When we traced this epidemic to its origin we found one boy was responsible for it. This boy had recently come from a similar institution in Fort Wayne. I wrote Dr. Bulson, and he investigated the institution there and found 125 cases of trachoma.

Dr. Bulson in his discussion has covered some of the things I wanted to say, but I would like to emphasize some of his points.

First, in reference to Prince's solution. It is ten percent solution of sulphate of copper *in glycerine*. One drop of this solution is put in ten drops of previously boiled water, left to cool. It is then used freely in both eyes, every four hours. The strength of the solution is gradually increased by leaving out a drop of water to the dose daily until one drop of the solution is used in ten drops of water. It must not be used any stronger, and it must be used as above. It will not admit of any modification.

Second, when we are forced to treat these cases mechanically there is no better way than to sandpaper the conjunctivæ of the everted eyelids. I like this better than the roller forceps.

Third, the differential diagnosis between follicuIosis and trachoma is difficult at times, but a frank case of trachoma should be difficult to recognize. Even the stretching of the eyelid will at times fail to give a positive diagnosis. When in doubt, treat the case as trachoma, but avoid violent means like grattage or even sandpapering the conjunctival surface of the eyelids.

Fourth, the sequelæ are numerous and oftimes tax the patience and ingenuity of the doctor—but that is another tale.

DR. JOHN R. NEWCOMB (Indianapolis): You have heard from Dr. Stucky the tragedy of trachoma, and it is a tragedy. But, gentlemen, we are fighting in the dark. It is not a fair fight so far, and we must have light on it. As Dr. Bulson mentioned, and as suggested at the Kansas City meeting of the Academy, why should the Rockefeller Foundation spend its millions in South America, when it could spend the same amount of money in a scientific investigation of trachoma and obliterate, in years to come, this horrible plague that is in our midst? It is right here with us. We find hundreds of cases in this city—yes, thousands. For that reason I say that none of you can diagnose trachoma. I defy any man in this room to make an absolutely accurate diagnosis of trachoma. It can't be done. As for differential diagnosis, it means nothing.

I simply wish to be a ditto mark to all that Dr. Stucky has said; but I beg of you to realize

that this situation is a disgrace to ophthalmology today. Let every ophthalmological association, every group of ophthalmologists, get back of this thing, get back of your bureau of investigation, and everybody dig down in his pocket and help.

DR. B. D. RAVDIN (Evansville): Somewhere in the foreign literature—perhaps Dr. Bulson may enlighten me—I read that one of the observers found that almost every one of the children who had trachoma responded to the tuberculin test, and by giving that test you can save time.

Personally, I have not investigated this question, but it seems to me that since none of us seem to know very much about it, we should try out these treatments that have been mentioned. Since the observers claim that children who have trachoma do respond to the tuberculin test, why not try it out here in America?

DR. D. O. KEARBY (Indianapolis): Not being an eye man I cannot discuss this paper except as it appeals to me from the horrible picture that Dr. Stucky has presented.

The thing that appeals to me is a point our chairman touched upon in his paper, and that is that we should go further back than having the Rockefeller Institute or the Government send an isolated man into some community to take up this matter. We should begin to teach the public some of these things. When you stop to think of the dollars that are spent in schools and on teachers, in order to raise up a child to fill a special position, or handle a job of some sort to make a few dollars, when there is not a single cent spent anywhere for the purpose of teaching him how to take care of himself—it is a tragedy, and I feel that somewhere (I don't know who is going to do it if the medical profession does not) there should be an organized educational effort, an arrangement made by which pupils in the public schools can be taught something with reference to how to prevent disease, rather than have them come to us for treatment after they have it.

DR. STUCKY (closing discussion): I greatly appreciate the generous and sincere discussion of my paper and I feel more encouraged about the future in regard to the solution of this great problem of trachoma than ever before, because I feel that genuine good will result from what has been said in the discussion. It is no exaggeration to say that the half has never been told regarding the tragedy being enacted by the scourge of trachoma in the mountains of Eastern Kentucky, and the problem is a Public Health one, because it concerns not only the people in the mountains but all with whom they come in contact. It is no reflection on the ophthalmologist who sees only a few cases each year when he says he is not familiar with the disease. In the first stage it is most difficult to differentiate true trachoma from other well known diseases of the eyelids.

The public must be taken into our confidence and educated to the real condition and danger that exists, and when it is aroused it will meet the situation as it always has done through assistance to and cooperation with the medical profession. Fortunately, so far, we have never had an epidemic of trachoma, but if we should and a similar percentage of the public were inoculated and afflicted as they were by influenza a year or two ago, the suffering and sorrow that would result is almost unthinkable.

I purposely did not say much about the treatment of trachoma, but I do not hesitate to say that I do not believe that grattage will cure the disease, though it puts the eye in condition to enable us to do more for them afterwards, and the subsequent treatment is most important. I think more and more of the old copper treatment for trachoma, especially for the patient to use at home. There is nothing superior to it, though I also use a ten percent solution of trichloracetic acid rubbed into the trachomatous lids. Wherever we have schools, public health nurses, and close attention to personal sanitation and hygiene we have greater success in dealing with the disease.

A CASE OF ECLAMPSIA WITH 42 CONVULSIONS

TREATED BY CAESARIAN SECTION, PHLEBOTOMY AND BLOOD TRANSFUSION: SURVIVAL OF BOTH MOTHER AND CHILD

W. D. GATCH AND W. D. LITTLE
INDIANAPOLIS, INDIANA

(From the Department of Surgery, Indiana University School of Medicine)

The patient, aged thirty years, entered the Robert W. Long Hospital on April 5, 1919, near the middle of the ninth month of her second pregnancy. (The first pregnancy had been uneventful and had terminated in a normal delivery.) There had been five convulsions within the last seven hours. Each convulsion had been more severe than the preceding one and the intervals between were successively shorter.

Six weeks prior to admission she had had an attack of influenza which had been followed by a marked albuminuria. At the age of ten years and again at the age of twelve years she had had a facial paralysis of the right side of the lower neurone type. As a child she had been obese but had become thin at the establishment of catamenia at the age of fourteen years. No other significant facts were elicited. The acute attack was ushered in by a suddenly developing

headache, epigastric pain, and blurred vision, followed by the convulsions.

Physical examination upon admission: Temperature 104.6 F. Pulse 110 and Respiration 24. She was a robust woman of the stout type, with dry skin and edema of the extremities. The scleræ were clear. The pupils were round and reacted to light and accommodation, with the left slightly larger than the right. There was some edema of the nerve heads. The thyroid showed moderate general enlargement. The lungs were resonant throughout, and the breath sounds were clear. No enlargement of the heart was found by percussion, no thrills nor shocks were felt, and no murmurs were heard. The liver dullness extended from the sixth rib to the costal margin in the midclavicular line. The spleen was not felt. The knee jerks were increased but equal. Urinalysis showed a heavy coagulum of albumin, many granular casts, and a few waxy casts. The blood pressure was 180 systolic and 120 diastolic. The fetal heart rate was 134 per minute and was heard in the left lower quadrant. Pelvic examination revealed a cervix which was undilated and rigid. From these findings cæsarian section was considered preferable to any method of vaginal delivery.

Treatment:

(a) Cæsarian section: This was done under light ether anesthesia immediately after admission to the hospital. Very little hemorrhage occurred. The abdomen was closed very securely. A living babe was obtained, but respirations were initiated only after considerable difficulty.

(b) Phlebotomy: This was resorted to only after some hours had elapsed and more convulsions had occurred. In all 1200 cc. of blood were withdrawn.

(c) Blood transfusion: In order to replenish the blood volume 625 cc. of whole blood were given, from the husband, by the Kimpton-Brown method. It was hoped that the fresh blood would exert a beneficial influence upon the course of the disease.

(d) Various supplementary measures. Morphine was given freely. At the very beginning a fluid intake of 3000 cc. per 24 hours had been instituted, and this was maintained throughout the course of the convalescence by means of normal salt solution intravenously and proctoclysis, and later by stomach tube as improvement of condition became apparent. Hot packs were given, for short intervals, on two occasions.

Convalescence. Subsequent to the cæsarian section there were no convulsions for two hours, during which time the patient roused sufficiently to inquire about the babe. Beginning after two hours and continuing for thirty hours there were 37 convulsions. In the last two hours of the period there were rapidly recurring seizures of from one to three minutes' duration, with intervals of from four to six minutes of coma. Once during this time the rectal temperature rose to 107.3 F. It was combated by means of ice packs and ice enemata. After the cessation of the convulsions there was profound coma for 48 hours, followed by a gradual recovery of mental and muscular powers. Aphasia, which was present at first, gradually cleared, although slowly. A paralysis of the right arm and leg changed to a weakness and finally there was complete restoration of function. The patient was discharged on the fortieth day after admission.

The course subsequent to the discharge from the hospital has not been entirely satisfactory. The child is vigorous and healthy and although too young as yet to give evidence of mental inferiority seems to be quite normal. The mother's mind has not recovered completely. At the present time, two and one-half years after the illness, her mentality is about that of a child of twelve or fourteen years.

The convalescence of the mother in this case presents nothing unusual. In fact paralyses, aphasias and affected mentality are rather uniformly the rule. However, recovery is unusual in a condition of such severity, and to just what therapeutic measure it is attributable is not plain.

Dold[1] [2] showed that blood serum would neutralize the toxic properties of certain tissue extracts. Obata[3] demonstrated that the ability of the blood serum of women with eclampsia to neutralize the toxic products of placental extracts was diminished or absent. From the above mentioned data Bell[4] [5] reasoned that blood transfusion was indicated in eclampsia and treated a case in April, 1920, by this method with recovery of the mother. The present case was treated in April, 1919, by transfusion as an adjunct to the supportive and eliminative means usually employed. It now seems that blood transfusion has a basis of scientific fact to recommend it in eclampsia and perhaps in the treatment of other toxemias of pregnancy.

Granting that placental extract is toxic when injected intravenously in animals we have, as yet, insufficient evidence to say that the placenta *in situ* is the source of the toxins which are thought to cause eclampsia and kindred conditions. However, we are justified, it would seem, in using blood transfusion in these cases since it offers hope of a lowered mortality and is eminently safe if properly carried out.

THE PHYSICIAN

SOME NEWER TENDENCIES IN PREVENTIVE MEDICINE*

By
FRANK B. WYNN
INDIANAPOLIS, INDIANA

Medical research in recent decades has given a distinctive bent to preventive medicine. The discovery of bacteriological causes of disease naturally and properly turned the eyes of public health agencies toward the infecting organisms and measures to prevent their dissemination. It has been a wonderful chapter in the history of the public health movement. What follows is not to be taken as a criticism of the progress made in the realm of sanitary science. Let the legitimate propaganda go on multiplying their beneficent influence. The exhortation offered is that we should not allow the brilliancy of the work accomplished in the field of infections to blind us to the urgent call of other public health work, separate and distinct from contagious and infectious diseases. In our enthusiasm and diligence in searching for specific causes in the test-tube or under the microscope, we have perhaps been too much inclined to forget the individual as a whole—the living, growing, reacting organism with complex phenomena which make up the warp and woof of life, in health and disease. Let us remember that the biggest problem in public health is now, and always will be, how to make the strongest possible individual, capable of fighting his own battles against disease-invasion—this rather than keeping him from coming in contact with the contaminating agency, important as this may be.

Advancement in education constitutes the chief boast of modern civilization. But if one applies the principles of scientific analysis to the methods in vogue, it does not take long to reveal gross faults which work both harm and injustice to many seeking the benefits of education.

Public schools and colleges are like so many mills into which children and young adults of all classes and capacities are dumped, with the expectation that they will be ground into uniform, superior mental and moral flour. The commercial miller would not be so foolish as to mix wheat, rye and corn, expecting thus to get a superior product acceptable to a critical public. Wisely he would separate the grain, give each a different treatment, and thus produce a fine marketable product. Not so in education. All must go into the same hopper, be ground between the upper and nether millstones of long usage, trusting to the sieve of routine examinations to strain out the unworkable materials, which are cast aside as refuse—weaklings, incompetents, failures, delinquents; in their life-work inefficient, discouraged, in the end oftentimes becoming a community burden.

A few years ago the manufacture and refinement of petroleum was a thing unto itself. What remained or arose in the course of the process was considered sheer waste which was cast aside. The application of scientific study and economic conservation has proved that the by-products of petroleum are of greater value than the oil itself. At the present time a similar waste is going on in the by-products of our present system of education—the supposed failures, delinquents and the like who are threatening to become public or private charges, but by proper direction at the right time and in the right way, may be conserved as useful citizens.

The observations here made are prompted in good part by the remarkable work of H. H. Goddard, director of the Bureau of Juvenile Research in Ohio. As he sets forth it is possible by means of the Binet and kindred tests to determine the mental level of the individual, his adaptability and intelligence in handling knowledge. Primarily the test was employed in the recognition of feeble-mindedness; also in the mental evaluation of delinquents and criminals.

During the world-war the plan was applied to the U. S. Army for the determination of those suited for over-seas service. By this means classification was possible according to capacity and adaptability. In the great conflict it was universally recognized that American soldiers were noteworthy for their ability to act promptly, with fine initiative and intelligence, when emergencies arose. The men had confidence in themselves which insured the dash and success which amazed the world. If the working out of mental levels has thus been demonstrated by army experience to be so practically valuable, does it not offer the strongest argument for applying similar tests and principles in our educational regime? Is it not far better that one should learn his true mental plane where his capacities will count, than that he should be forced to higher levels to which he is not adapted and from which he will fall into the depths of failure, and discouragement? The highest function of education is not to force upon one from without unassimilable knowledge, but rather to work from within out, enabling the child or youth to find himself. Show him his own powers and limitations and fire him with zeal for the accomplishment of those things which he can and ought to do.

Educational workers the country over are awakening to the need of applying intelligence tests in the classification of pupils and students. Columbia University makes such a requirement of those entering the freshman class. In the

*Eighteenth of a series of articles by Dr. Wynn which appear regularly in THE JOURNAL.

State of Indiana a very noteworthy and exhaustive research has recently been completed by Wm. F. Book, head of the Department of Psychology in Indiana University, in collaboration with Oscar H. Williams, of the State Department of Education. I have been privileged to examine the proof of this remarkable, forthcoming volume. To 5,748 seniors in high schools, modified Binet tests were applied. Among the many interesting things revealed was the fact that 25 percent of the superior high school seniors had no intention of taking a college course, whilst from 65 to 70 percent of mediocre students had made definite plans to attend college. This would appear to indicate that the schools as at present conducted are not conserving their best intellectual material for future advancement and use to the State.

Estabrook reports that in an orphans' home of Indiana, in which the Stanford Revision of the Binet test was used on 140 children, 53 were of average mentality, 37 retarded, 12 probably mentally defective, and 38 definitely feeble minded. The latter illustration shows how grossly unjust the present system is in expecting this large proportion of sub-normals to measure up to the average standards in school work.

The writer has given these commendable examples of work in progress in the field of education, to show wherein it seems to me the trend is at fault. Goddard and Book, who may be characterized as distinguished pioneers in this field of practical research, are rendering inestimable service to the cause of education as well as to the sociological status of the community. Both argue with convincing power that this movement is one of vital and practical interest to democracy—giving to the child or young adult his rights for the development of the best there is in him.

If the writer seems presumptious in criticizing the methods pursued, it is not on the basis of experience as a pedagogue but on the ground of observation as a physician. Medical practitioners have an opportunity clinically to observe the mal-adjustment of children and youths to the work they are expected to do. In the light of this observation it has seemed to me the scope of the work thus far attempted is too narrow. It omits prime essentials if the largest service to the individual is to be achieved and the greatest good to the community attained.

In the main the suggestions offered are not new but as old as history itself. Only a change in method is proposed. I refer to the proper development in the growing individual not only of the mental but of the emotional and moral traits as well. Because organized religion has always maintained control of this field in the past, offers no justification on the part of scientists ignoring the subject, especially since it is fundamentally a physiological problem.

In discussing the question let it be granted that in man, a fine mentality constitutes one of the crowning ornaments of the human temple. But in this as in all other building, are not the foundation stones all-important—truthfulness, fidelity, courage, aspiration, faith, hope? On top of this foundation must there not be builded the brick of patience, cheerfulness, sacrifice, industry, frugality, friendliness and helpfulness? And how necessary that the whole be bound together by the cement of sound wisdom and poise!

So far as the materials entering into a well-rounded life are concerned, it seems to me the most practical classification for the purposes of education and moral training is to designate those materials as mental, temperamental and moral. By all means let the determination of mental levels so admirably begun go on; but do not wisdom and common sense tell us that it should go hand in hand with temperamental and moral evaluation? There is no valid reason why the latter characteristics of children and youths should not be scientifically worked out by means of tests just as the Binet test has been applied for the evaluation of mental capacity.

In further argument for this contention let me ask what person of collegiate training does not look back with amazement at the subsequent careers of his classmates? There was one who by all mental tests should have attained fame, now fallen by the wayside, held back by temperamental or immoral handicap. Another who was considered almost a dullard has progressed to fine achievement and large usefulness. The call of the age in educational circles is for a three-fold evaluation of children and youths by well devised tests—mental, temperamental and moral. In this way it should be made possible for the individual to find himself —to learn his weaknesses, capabilities and powers, to the end that he may use them for success and contentment. The purpose of education is not so much to feed into the human machine great quantities of knowledge which it can never thresh out, but to properly adapt the material to the mechanism. Equally important is it to make sure that the machine is in order and runs well.

Since this is essentially an educational problem it may be asked what relation has the physician to it? In reply it should be said that to us come the end-products of a faulty educational system—the social and vocational misfits, suffering from all manner of functional diseases—neurasthenia, hysteria, melancholia; failures in the life-struggle resulting in moral delinquency,

pauperism and crime. Medical wisdom looks upon much of this as bad mental and moral drift, which taken before the flood of failure, might have been kept out of the social stream. Here then is a newer and higher type of preventive medicine, in which we should and no doubt will in the years to come play a large part.

In connection with these reforms in educational methods, the physician should at least be advisory; and it is not too much to predict that in the near future, the physician-pedagogue will become a fixture in both the collegiate and public school system. The all-time health officer has already proved the value of his services in the public school system. Whilst as at present constituted, his function is to spy out infections and physical defects, the future will demand of him a larger and more difficult service. He will become the arbiter of mental, temperamental and moral capacities in children and youths, enabling their proper classification for educational work. Such men will be among the most highly trained educators and will command correspondingly high salaries. Thoroughly grounded in the fundamentals of medicine they will also require special training in public health and mental hygiene, comprehending both normal and pathologic psychology. It will be a field to stir the highest aspirations of the teacher and offer to him the rewards of great achievement in personal helpfulness.

LESLIE'S ON CHIROPRACTIC

There is no information which the public needs more, than that which will reveal the actual character of the claims made by certain medical cults—chiropractic in particular. This information is now forthcoming through a series of articles addressed to the public. Six articles entitled "Is It Chiro-*Quack*-Tic?" by Severance Johnson are now running in *Leslie's Weekly*, two installments having appeared in the issues for January 7 and January 14. The medical profession has from the beginning recognized the ridiculously unscientific character of the claims made by these cultists and has repeatedly shown that chiropractors are working directly against public welfare; that they attempt—and with some success—to break down medical practice laws, and frequently and openly violate these laws, aided and abetted in doing so by the so-called colleges that are grinding them out. But the public also has large financial interests at stake. Public funds are now being appropriated to help educate competent medical men. To conduct a medical school today costs several times what the institution receives from students' fees, and this deficit is being offset either by state appropriations or private endowments. The expense is being further added to by a gradually increasing provision for scholarships for deserving students who are unable to pay tuition fees. Are the benefits of these expenditures to be lost or dissipated through the spread of chiropractic? Because of the great expense involved in training competent physicians, medical schools conducted for profit have practically disappeared. But the place of the old, low grade, commercially conducted medical school is now being taken by chiropractic schools. Within a score of years, by charging maximum fees for a minimum of education, a long-haired but shrewd advertiser has amassed millions through conducting a chiropractic "college". A comparison of the brevity of the "professional" course and the common school education required for admission, with the ten or eleven years of high school, collegiate and professional instruction required to develop a competent practitioner of scientific medicine should at once show the inadequacy of the training obtained by chiropractors. The manner in which chiropractors disclaim the need of diagnosis and flout the fundamental sciences of chemistry and bacteriology should reveal to any intelligent layman the utter unreliability of chiropractic as a system of healing. It is high time that the public became fully informed in regard to the workings of this organized system of quackery, and *Leslie's Weekly* is rendering the public a great service by publishing the information.—*Journal of the A. M. A.*, Jan. 14, 1922.

TREATMENT OF INFANTILE PARALYSIS AS BASED ON PHYSIOLOGIC INDICATIONS

In order to restore function in a muscle, Henry O. Feiss, Cleveland (*Journal A. M. A.*, Jan. 14, 1922), has tried to apply function that is as consistent with the normal conditions of life as possible. This means not massage and electricity, which are only local in their effects, but the striving to obtain function through physiologic agencies. To be considered are voluntary effort, subconscious and reflex (induced) movements. It is not only important that these be applied as soon as possible, but also that they be applied strenuously and continuously.

SOCIALIZED MEDICINE

It is evident that a very large proportion of the medical men in this country are not interesting themselves sufficiently in opposing the various plans, put forth by erstwhile leaders in our profession, which ultimately will lead to socialized medicine. The subject is a vital one, and has to do with the very life of the medical profession as a profession, aside from being of the utmost importance to the welfare of the people at large.

Perhaps it was to be expected that in this day and age, when there is so much social unrest among all classes of people, largely due to a misconception of existing conditions and the causes, that there also should be a little unrest in the medical profession. However, there always have been and always will be reformers, and men with visionary but impractical ideas, though at the present moment we are afflicted by too many of that kind, and it so happens that most of them are men occupying more or less prominent positions in the professional world. In fact, most of the Utopian but impractical schemes which work to the detriment of the medical profession and indirectly are harmful to the public, have not originated in the minds of laymen but are advocated and sponsored by prominent medical men who, if entirely honest in their convictions, have not analyzed the subject sufficiently, or, and this is more often the case, have personal ambitions to satisfy.

Some very good men see only the Utopian side of the question and are led to support modified forms of State medicine without realizing what it means and where it will end. No one objects to that feature of State medicine which has to do with public health work as carried on at the present time, even though we confidently believe that the work could be done better as a private enterprise not subjected to political jugglery. What should be objected to is any scheme, under whatever guise, that leads to the furnishing of all medical and surgical advice and service by Federal, State or municipal employees, which in its ultimate end will result in bureaucratic medicine with all of its vicious effects and in making the people wards of the State.

As an evidence of the trend of our leaders, we call particular attention to the attitude of the University of Michigan, which through its president, as reported in the daily press and in the *Illinois Medical Journal,* openly served notice to the medical profession that the University of Michigan virtually intended to take charge of or superintend the practice of medicine in Michigan. Following on the heels of this announcement, Dr. Hugh Cabot, dean of the Medical Department of the University, proposed a scheme for the establishment of what he calls "community clinics" in many sections of Michigan, to be conducted by and under the control of the Medical and Surgical Staff of the University of Michigan, a select few of the medical men of Michigan in the various communities served to be the nominal representatives of the University in the conduct of these clinics. As pointed out in THE JOURNAL, November, 1921, this starts out by creating caste in the medical profession, known to the public as such, which is bound to cause dissensions, but it also paves the way for the operation of a more comprehensive plan directly under the control of the State with all of the attending vicious results which inevitably would follow. In the end the medical profession loses out, private practice is largely if not wholly abolished, and we have bureaucratic medicine with all its ills! Those who are sponsors for the development of such a condition of affairs fail to appreciate the fact that when we get bureaucratic medicine there will not be any such thing as preference because of competency or integrity. It is a question of politics and pull, first, last and all the time. The man of ability, experience and initiative will be ruthlessly sacrificed on the altar of expediency. As a final act to the drama the poor suffering public pays the penalty by receiving poor service, impersonal attention if not studied indifference, so common to all public officials, and the people are reduced to mere wards of the State. We want none of it, but we will have it unless some of the leaders in the medical profession quit their everlasting advocacy of wild and impracticable schemes such as proposed by Dr. Hugh Cabot and his like.

UNETHICAL MEDICAL ADVERTISING

A newspaper clipping bureau furnishes THE JOURNAL with clippings or abstracts of personal news notes and articles of a medical nature from practically every newspaper in Indiana. Very naturally we are amused and at times provoked to note the frequency with which some Indiana medical men, a few of them prominent

and a limited number being officers of medical societies, permit their names to appear in the daily papers, often in repetition, concerning cases in which more or less so-called wonderful cures have been accomplished. In practically every instance the "write-up" gives indication of either having been written or inspired by the doctor whose name is mentioned. Lately THE JOURNAL office has been flooded with newspaper clippings and even letters calling attention to the most flagrant abuse of ethics by certain members of our Association who seemingly court newspaper advertising and notoriety.

It is conceivable that occasionally a doctor's name may appear in print in connection with a news note concerning some patient who has been given attention and the publicity occurs without the knowledge or consent of the doctor connected with the case, but such instances are rare and such newspaper articles do not contain accounts of rare operations told in technical terms nor refer to wonderful or miraculous cures. Furthermore, the average newspaper does not publish these glowing tributes without knowing that they will be acceptable. In fact newspapers are quite willing to conform to the wishes of the medical profession that advertising of such character be eliminated.

The fact of the matter is that this unethical newspaper advertising and cheap notoriety, if not sought, is sanctioned by some Indiana doctors, and it is time that our local medical societies call for an accounting. We fully realize that the rules of medical ethics are broken often by many of our medical men, and when we attempt the "cleaning up" process we ought to touch many subjects, but we might begin on newspaper advertising which is the most flagrant abuse of all at the present time. We again suggest, as we have suggested once before, that county medical society secretaries keep a scrap book and paste in it all of the newspaper clippings concerning members which appear to be an abuse of medical ethics, and ask the offending members for an explanation. If any guilty doctor refuses to explain or to show that he has been the victim of the kind of publicity of which we complain, without his knowledge or consent, then it is time to ask for his resignation from any reputable medical society and list him among the quacks where he belongs.

PROMISCUOUS ADOPTION OF MEDICAL INNOVATIONS

That the medical profession as a unit should be opposed to all schemes and proposals based on theory alone is expressed in an article by Edward H. Ochsner, of Chicago, and abstracted from the *Ohio State Medical Journal*. It is his belief that physicians should look with disfavor on all propositions:

1. *Which are not absolutely necessary.*
2. *Which introduce new evils.*
3. *Which advertise a few at the expense of the many.*
4. *Which appropriate without fair remuneration the skill, knowledge and time of the physician.*
5. *Which are palliative instead of preventative or curative.*
6. *Which further place medical men under lay supervision.*
7. *Which unduly interfere with the individualism of the medical man or are paternalistic.*
8. *Which have a tendency to pauperize the public and thus destroy the self-respect and self-reliance of the people.*

In the following paragraphs Dr. Ochsner briefly considers each one of the above eight tests:

"1. I believe that the medical profession of America renders better service to its fellow men than does any other group of citizens. I believe that the average American citizen has better medical care than the average citizen of any other country on the globe. If these two statements are true, what is the need of any of these new fangled schemes? Of course, we must have progress, but—

"2. Let us be very careful in adopting new schemes to see that they do not introduce new evils—evils which may be greater than those we are trying to correct. It is about time that we physicians look where we are stepping. Make sure first that we are going in the right direction before we adopt any scheme. Then if it proves good, adopt it, but let us not keep a-moving just for the sake of moving.

"3. Let us analyze the real fundamental reasons for the establishing of free clinics and dispensaries in Chicago as elsewhere. You will find four reasons —two are legitimate and two are not. The legitimate ones are to provide proper medical care for the sick poor, and to provide teaching material for medical students. The illegitimate ones are for the purpose of advertising a certain doctor or group of doctors, or to act as a feeder for a certain hospital. When we adopt new schemes let us be careful that they are for the benefit of the rank and file of the profession and the people and not for the aggrandizement of a few.

"4. We should also oppose every scheme which appropriates the time, skill and knowledge of physicians without just, fair and reasonable remuneration. Why? Because anything which continuously works to the disadvantage of the medical profession will in the end work to the harm of all the people of this country. Next to stability of government, honesty of administration and general intelligence of the people, the welfare of a nation depends more upon the quality of medical service which is rendered to its citizens than upon any one other thing. The longevity, health, efficiency and happiness of a people depend more upon the integrity, ability and industry of its medical profession than upon anything else. If these two postulates are true, and I think they are, then anything which hinders medical progress and which will have a tendency to prevent suitable young men from entering the profession is inimical to the best interests of the whole nation.

"5. We should oppose every scheme which is a palliative instead of a preventative or curative. It is an axiom in medicine and surgery and should be in political economy that a palliative must not be used continuously for any considerable period of time unless the case is hopeless. These people who want to reform everyone except themselves are continually

advocating the continuous use of palliatives and this is a serious economic mistake. We physicians have learned better. We use morphine only to bridge over a period of short stress or to alleviate a hopeless condition.

"6. We should oppose any scheme which has a tendency to further place medical men under lay political supervision and control. Medical men are being more and more dominated by laymen. This is a bad thing for the medical profession and a very serious obstacle to medical progress. Our hospitals are being more and more dominated by lay boards; our medical colleges are virtually completely under the control of laymen. Quite a number of our medical schools have deans who are not medical men, who cannot practice medicine in the state in which they are deans because they are not medical graduates. Another group of our medical deans while they are graduates from medical schools are unfit to practice medicine because they have had no practical experience in the practice of medicine. A very large group of our medical teachers are not medical men and while the old system of ownership of medical colleges by physicians had many objections, the new system has many objections which are even more serious. Our national, state and county institutions with their thousands of patients are controlled by lay boards. In Europe where Compulsory Health Insurance has been in force, this control is so menacing that medical progress has practically ceased. Frederick L. Hoffman is reported as having found a very amusing incident in his recent investigation of the workings of the Compulsory Health Insurance act in England. An English panel doctor prescribed fifteen capsules for a patient but the patient got well when he had taken nine. This physician was called before the lay board, censured and fined because the lay board claimed that he should have known that the patient needed only nine capsules for his recovery. How would you gentlemen like some lay board appointed by Hinky Dink, Bathhouse John, or John the Pow, or some other group of equally powerful politicians in this city, any one of whom has more political influence than all of you combined, to tell you just what you may and may not do in the practice of medicine?

"7. It is time, gentlemen, that the medical profession wake up. I am not a pessimist but the medical profession is today facing the most serious crisis that it has ever faced in the history of American medicine. Most of these schemes interfere with the individualism of the medical man. There can be no medical progress without individualism and without individual liberty. In political economy I believe in *voluntary cooperative individualism*, in other words *democracy* as opposed to *socialism and autocracy*. I am opposed to each and every one of the fifty-seven varieties of socialism because it interferes too much with individualism and dampens personal enthusiasm and incentive. I am opposed to autocracy for much the same reason.

"8. We should oppose any scheme which has a tendency to pauperize the public or which robs the people of their self-respect and self-reliance. Practically every eleemosynary institution is evidence of some fault in our economic system. It may be necessary now but our supreme effort should be to make all such institutions superfluous. We must have certain charitable institutions today but outside of charitable institutions for mental, moral, and physical defectives who are unable to provide for themselves, the time should come and must come and will come, if we progress in civilization, when there will be no other charitable institutions because charitable institutions, no matter how carefully managed, have a tendency to take from independence its proper pride and from mendicancy its salutary shame. Shakespeare said very well, as he always said very well:

" 'Who steals my purse steals trash; 'tis something, nothing;
'Twas mine, 'tis his, and has been slave to thousands;
But he that filches from me my good name
Robs me of that which not enriches him
And makes me poor indeed.'

"If Shakespeare had lived in this present day with all the innumerable welfare schemes in operation and contemplation he would have added in very much better English than I can command the following thought: 'And he who deliberately robs any man of his self-respect and self-reliance is infinitely worse than even the thief or the blackguard. He is an enemy to society and a menace to free institutions.' Free institutions depend upon self-respecting citizenship and many of these welfare schemes rob men and women of their self-respect and self-reliance.

"The activities of medical men, as medical men, can be classified into three functions: First, sanitation and public hygiene; second, the teaching of personal hygiene, and finally, the treating of disease. The first is distinctly the function of the state and the last is distinctly the function of the private practitioners of medicine."

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, suhc as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

COUNTY Medical Society Secretaries are asked to notify us of any alterations or corrections that should be made in the county Medical Society Directory on advertising page six of this number of THE JOURNAL. Unless this directory is correct, it is of no service, but it can only be correct through the assistance of the secretaries who heretofore have given us very little help.

THE zoologists of the United States Department of Agriculture have discovered that carbon tetrachloride is very effective as a destroyer and dispeller of intestinal worms in humans as well as animals. It is very effective in treating round worms, but quite recently it has been found effective in animals infested with hook worms and gives promise of also being effective in the treatment of hook worm in the human.

THE series of articles entitled "The Physician", by Dr. Frank B. Wynn of Indianapolis, which has been running in THE JOURNAL for over a year, probably will be completed with the February or March number. At the earnest solicitations of many who have read the articles, Dr. Wynn will publish his contributions in book form. The edition will be limited and we suggest that those who would like to have the book ought to place their orders with Dr. Wynn at an early date.

AT the Philadelphia session of the American College of Surgeons the medical anesthetists came in for a scoring at the hands of Dr. Charles H. Mayo when he indicated that some of the legislative acts sponsored by the medical anesthetists have not been in the interests of public health but to the advantage of the anesthetists. We are quite in sympathy with the idea of obtaining more trained anesthetists, but we are not in favor of legislation that is so drastic that it places the anesthetic responsibility entirely in the hands of those who are considered expert.

AT the annual meeting of the Indiana Chiropractors' Association held at Evansville in November, plans to raise the standard of the profession (?) were discussed, and a law creating a State Board of Chiropractic Examiners without any expense to the State was advocated. We fail to understand why it is necessary to go to such trouble. The chiropractors are practicing without let or hindrance at the present time, and what more do they want? A law will not help them any. Indiana should wipe out all restrictive laws pertaining to any feature of the healing art. If we can't enforce what laws we now have, why have more?

LESLIE'S WEEKLY has begun a series of articles on what is called in the title "Chiro-*quack*-tic". The articles are written by Severence Johnson, and it is claimed that his articles are based upon a neutral, comprehensive and painstaking inquiry concerning chiropractic, the new method of drugless healing. Inasmuch as the followers of chiropractic, now claimed to be over a million in number, have announced that they are determined to exterminate the regular medical profession, perhaps the series of articles by *Leslie's Weekly* will serve a purpose in acquainting the thinking public with the facts concerning this new species of quackery which is threatening the lives and health of the people and is such an arrogant piece of quackery as to merit the attention of the public. Perhaps there are other periodicals placing truth above financial gain that will be willing to discuss chiro-*quack*-tic.

INDIANA has many hospitals. A very limited number are approved. There must be something radically wrong with the rest, and they ought to brace up on their qualifications. Is it ethics, quality of work done, or lack of equipment and facilities? Whatever the cause, we are sorry that more are not up to the standard. According to the honor role of hospitals published by the American College of Surgeons, Indiana is represented as follows:

Indianapolis City Hospital, Indianapolis.
Methodist Episcopal Hospital, Indianapolis.
Robert W. Long Hospital, Indianapolis.
St. Anthony's Hospital, Terre Haute.
St. Elizabeth's Hospital, LaFayette.
St. Joseph's Hospital, Fort Wayne.
St. Margaret's Hospital, Hammond.
St. Mary's Hospital, Evansville.
St. Mary's Mercy Hospital, Gary.
St. Vincent's Hospital, Indianapolis.

SOME doctors take particular pleasure in being nastily independent. They think it is smart to take no suggestions or advice from anyone, and when they are asked to lend a hand in promoting something of direct interest to the medical profession as a whole they find delight in offering opposition openly, or silently through failure to cooperate. Is it any wonder that we do not accomplish more when it is so difficult to get the public or legislators to think along right lines in the consideration of medico-public questions? How often do we hear the statement, "You doctors never hang together"? It is true! Let us turn over a new leaf and show the public that we are a unit for the things that are right and for the best interests of all concerned. If we do this we will have more and better legislation for the maintenance of right medical standards, and we will head off the idiotic socialistic schemes which eventually will end in bureaucratic medicine.

IT may seem presumptuous, or perhaps unnecessary, for us to call the attention of our readers to the advertising pages, but there are some members of our Association who do not seem to appreciate fully the effort we are making to protect their interests by keeping them posted concerning trustworthy firms and trustworthy products. Every month we publish a list of the pharmaceutical preparations that have been approved by the Council on Pharmacy and Chemistry of the A. M. A., and we also call attention to some preparations of either questionable character or perhaps determined as frauds. Our advertising pages contain no announcements concerning preparations that are not thoroughly trustworthy. We invite patronage of the advertisers not alone because the advertisers are worthy of patronage but because

the advertising and the income it brings enables us to print a larger and better Journal.

WELL, Well! Michigan is waking up! The January number of the *Journal of the Michigan State Medical Society* publishes the Cabot controversy and editorials that appeared in our Journal and, in addition, a number of editorials and editorial notes of their own touching upon the efforts of erstwhile medical leaders to socialize medicine. With New York, Ohio, Illinois, Indiana, and now Michigan rising up in opposition to some of the schemes of the uplifters which, if carried to fruition, would destroy private medical practice, it may be that other states will see the light and join in the effort to not only protect but save the rank and file of the medical profession. As one thoughtful and analytical medical man has stated, "The average doctor has his face to the sun and does not see the overwhelming storm coming from behind and threatening to destroy him." We hope he will wake up before it is too late!

A YEAR ago we had occasion to call attention to the fact that some of the A. M. A. officers reserve all of the available rooms at the leading hotels in the city where the annual session of the A. M. A. is to be held, and then parcel out the rooms to their personal friends. As a matter of fact, this is a species of discrimination and unfairness that should be prohibited at future sessions of the A. M. A. The rule "first come, first served" should prevail, and while the A. M. A. officers may succeed in getting the cream of the hotel reservations, they could not prevent others from having at least a fair show of getting the accommodations desired. We appreciate the fact that there are other hotels in St. Louis where if one "stands in" with the Chairman of the Hotel Committee, reservations for the St. Louis session may be made, but it is the principle of the thing which arouses our ire. The A. M. A. is a large democratic organization, and it is not supposed to be run in the interest of a few.

CHIROPRACTORS of California are making a hard fight for recognition in that state. Last November they succeeded in filing initiative petitions qualifying to place on the 1922 ballot a measure to be known as the Chiropractic Examiners' Act which would create a state board of chiropractic examiners to license chiropractors. Signatures to this petition were secured largely by women and girls, hired especially for the work, standing on street corners and in front of public buildings, petitioning all passers-by, who, in accordance with the usual gullibility, were willing to sign anything which did not entail the spending of any money, without even making inquiry concerning the nature of the petition they were asked to sign. A similar measure was defeated at the last session of the California legislature, and since that time a number of prosecutions of chiropractors practicing without license have been made. It is imperative for the medical profession of California to acquaint their lawmakers with the true facts concerning chiropractic and its fraudulent claims.

THE Board of Trustees of the A. M. A. has up for discussion at the present time the question of the best methods to be employed to educate the public regarding medical matters. Within the next six months a thorough survey of the whole question will be undertaken in such a way as to bring to light all the facts. In connection with this matter the subject of State Medicine will be considered. One of the trustees has publicly stated that there are evils lurking in certain partially organized plans, particularly the diagnostic clinic, and the latter will come in for a thorough survey in order to determine whether diagnostic clinics are conducted for private gain or for the public good. The health center schemes, tuberculosis clinics, venereal clinics, and Red Cross undertakings will be included in this survey. That the survey will be exhaustive and the conclusions dependable is guaranteed by the character of the investigators. Let us hope that it will result in the recommendation of a constructive program that if carried out will safeguard the interest of the medical profession individually and collectively, while at the same time it insures the greatest good for the people served by the medical profession.

MANY prominent clinicians and especially a few well known syphilologists always have considered inunction as the most efficient method of giving mercury. The inunctions are not used by many because (1) they are dirty and disagreeable; (2) they are liable to lead to discovery; (3) and when the preparation remains on the skin for such a length of time it is more liable to set up a folliculitis. In an article entitled "The Clean Inunction Treatment of Syphilis with Mercury", from the department of dermatology and syphilography of the Cleveland City Hospital and from the Western Reserve School of Medicine, published in the *Journal of the A. M. A.*, December 24, 1921, the point is made that these objections may be overcome by cleansing the skin and removing the superfluous mercurial ointment after a thirty minute rubbing. From one to two drams of the mercurial ointment is rubbed into the skin every night, and a different place selected each night in order to avoid dermatitis. All superfluous ointment remaining on the skin may be

cleaned off immediately after the inunction without lessening the mercurial effect. The authors think this is a distinct advance in the therapy of syphilis.

WHILE much has been done to prevent cancer and other malignant tumors, the death rate is steadily increasing, as evidenced by the statistics recently issued by the government Census Bureau. The statistics seem to show that the white and colored races are equally susceptible to cancer, but both races seem less susceptible in the South than in the North. There were approximately five thousand more deaths in 1920 than in 1919 and eight thousand more than in 1918. The statistics seem to indicate the necessity for more wide-spread knowledge concerning the cancer problem, including the necessity for early skilled attention to any suspicious growth. Another interesting feature of the late federal census report is the announcement that the trend of the tuberculosis death rate is downward, the total number of deaths for 1920 being ten thousand less than for 1919, and twenty-two thousand less than for 1918. Unquestionably this lower death rate is due to the effects of a persistent propaganda to acquaint the public with the cause and treatment of the disease. Inasmuch as the total deaths from cancer are approximately seventy-three thousand, against one hundred thousand for tuberculosis, the need for dissemination of knowledge concerning cancer is now as great as for tuberculosis.

AT the conference of State Medical Society Secretaries held in Chicago during the month of November, Dr. Frank Billings, of Chicago, made some pertinent remarks concerning the necessity of considering the general practitioner and how to improve his status and his knowledge when discussing medical uplift schemes. Touching upon the economic side of the subject Dr. Billings said: "When you say it is not worth while to study medicine because of the economic conditions of today, it simply means that there are not enough young men today who possess the moral stamina. If a young man is qualified, if he is honest, if he is animated by a desire to give service, and will practice medicine, regardless of what he may get out of it in a financial way, he cannot keep patients away from him. We fear social medicine, and the tendency since the war has been for national organizations and for the government to favor paternal medicine, but it will never succeed. In the poorest hospitals in this country the average patient gets better treatment than the discharged soldiers have had. You may talk of any health work you please, but any scheme centralized in the federal government or centralized in the state will fail, for it is axiomatic that any work of value for the welfare of the people must be done by themselves and paid for by themselves."

WHAT can be accomplished in the way of developing a wide-awake and progressive medical society is demonstrated by the standing and work of the Muncie Academy of Medicine. A few energetic and enterprising medical men in Muncie decided that it was possible to instill new life into their medical organization, and at once began a campaign by preparing scientific programs that no doctor within a radius of fifty miles could afford to miss. Outside talent was invited, and prominent medical men from various sections of Indiana as well as from other states have contributed to the programs. The interest in the meetings has grown until the attendance probably ranks with the attendance at any of the medical meetings in the state, not excepting those of the Indianapolis Medical Society where the number of members ought to count for large meetings even in dull times. What has been accomplished at Muncie can be accomplished to a greater or less extent in every county in the state. All that is required is a little push and enterprise on the part of a few men, especially a wide-awake secretary, coupled with that spirit of unselfishness and optimism which banishes professional jealousies and the too oft encountered habit of so many doctors to shirk responsibility or, to use a slang phrase, "let George do it." Muncie is on the map medically, and it speaks well for this year's session of the State Medical Association which will be held in that city. Of far greater import is the scientific and social work being done for the benefit of the medical profession of Muncie itself. The example is worth following by other local medical societies in the state. In fact what has been accomplished in Muncie should shame some of the larger cities where little evidence of enthusiasm exists.

PERHAPS a compromise concerning the training required for nurses will settle our nursing problems in a fairly satisfactory manner. The suggestion made at the meeting on Hospital Standardization at Philadelphia is worth considering and it is that a two years' course should be made the minimum standard of nurses' training, but that provision be made for postgraduate work, with a special diploma for advanced training. At present nurses are compelled to study and labor diligently for three years after having achieved a high standard of general education. They are over-trained for nurses and under-trained for physicians. The foundational

requirements are too high for the average demand. On the other hand, in all fairness, provision should be made for the specialized nurses who assume added responsibility in positions such as technical assistants, or where there is opportunity for securing personal distinction. There is no need of lowering the standard of the nursing profession, but there is an urgent need of a provision for a very large number of nurses of the practical type not so technically trained as our present day graduate nurses, but possessing sufficient knowledge of every day nursing to make them of service to hundreds of thousands of patients in moderate circumstances who neither demand nor would accept charity, but are not able to pay the wages of the highly trained nurse of today.

THE tendency toward ultra specialization in medical practice is on the gain if we may judge by not only the increase in the number of specialists but in the lessening number of the good old fashioned general practitioners. Perhaps it is but natural to avoid the unpleasant features of the practice of medicine, and to desire comfort, leisure, regularity of habits for work as well as play, not to be obtained when engaged in general practice, and yet there are many occupations that are less pleasant as well as less desirable than the general practice of medicine. In fact the general practitioner, if he decides to do so, can be about as much of a master of his hours of work as a specialist who confines himself to office practice, and he not only is much healthier for the outdoor exercise entailed in making calls, but the growing recognition of his value on the part of the public insures an increased competence. There was a time when the specialist seemed to reap a harvest in remuneration, but it is a question if that time has not passed, for with the increase of competition, if we may call it such, incomes of many specialists have been dwindling. A recognition of the value of the general practitioner is seen in the attitude of some rural communities that now are advertising for general physicians with a guarantee of more than a living income. In fact the inducements offered by some rural communities in need of general practitioners assure a professional income that is greater than that obtained by many general physicians located in cities where living expenses are greater. Perhaps within the next few years there will be a more wide-spread recognition of the fact that we already have too many specialists and in consequence a tendency to medical astigmatism. When that time comes more medical men will realize that the well educated and well trained general practitioner is the king bee among medical men, and whose services are most sought and most appreciated by the public.

IT is regretted that medical laws in practically all of the States of the Union are trampled under foot in a ruthless manner. No doubt the regular medical profession is responsible for this as a direct consequence of the apathy that exists among doctors as a class when it comes to doing anything for the common good outside of purely professional work. Boards of medical registration and examination have been derelict in duty, but their dereliction has been due to failure on the part of medical men to cooperate in upholding medical laws by vigorously prosecuting all offenders. We would hear little or nothing of pseudo medical cults if the first transgressor had been prosecuted. Medical laws are for the protection of the public and not for the protection of the medical profession, but the public fails to appreciate the fact because those who know the dangers of quackery have failed to impart the information to laymen. At the present time we might as well be without medical laws, for in many of the states, and notably in Indiana, anyone can practice medicine, and to do it doesn't require even a passing acquaintance with a medical college or medical books. Quite recently in one of our Indiana cities a chiropodist operated a deformed foot, resulting in an infection which the chiropodist treated for some time, or until the patient, in disgust, consulted a regular physician. The same chiropodist arranged to operate, under general anesthesia, another patient with a deformed foot, and a dentist had agreed to give the anesthetic notwithstanding the fact that no effort was made to determine the physical condition of the patient who had a heart involvement which would greatly increase the risk even in the hands of an expert anesthetist. Men and women, even young boys and girls, without even an ordinary school education but possessed of a chiropractic diploma secured after a few weeks of indifferent schooling, are practicing upon the sick and disabled. The opticians with no medical training of any kind whatsoever are treating eye diseases, and the next thing we know the plumbers will be doing appendicitis operations. Under such conditions why have medical laws?

IN a letter to the *Journal of the A. M. A.*, December 10, 1921, Dr. Frank Billings of Chicago says some pertinent things concerning group practice, diagnostic and pay clinics. While recognizing that modern clinical medicine embraces such a vast field of knowledge that it is beyond the capacity of any individual to acquire the necessary learning, experience and skill to care efficiently for all patients, yet it is Dr. Billings' opinion that a painstaking general practitioner is able to make a correct diagnosis in a large majority of all patients with

the readily available small laboratory and instrumental equipment, and a thoroughly trained use of proper senses. A specialist may be eminently qualified in his own field of practice but usually he is professionally incompetent outside of it. Today the public suffers because many general practitioners neglect to make the examination and record all of the patient's condition, and in consequence the treatment and management given are slipshod, haphazard and often ineffectual. In fact one of the chief reasons for the growth of the cults is the failure of the general practitioner to give the best that is in him to the service of his patients. *As a matter of fact the application of all the refinements of laboratory and instrumental assistance in making a diagnosis are required in a small percentage of patients,* and just as long as the family physician fails to render the service that he can and should render, there will be a demand for group practice. The trouble with most group practice and diagnostic clinics is that they are conducted selfishly and for questionable purposes in the interest of the individuals forming the staff or the group. There is a distinct need of facilities for diagnosis and treatment by a qualified group of specialists for those patients who suffer from a small group of ailments. However, the sick public that requires this expert service is relatively small. The larger number requires the service of the good, honest and responsible practitioner who will give the best that is in him. If he does this he will not lack for patients or for financial reward.

In concluding his interesting communication Dr. Billings says, "Finally, to judge from known conditions in Chicago, there is a lack of the old fashioned, resourceful family physician in the larger cities. Many private practitioners whose chief practice a few years ago consisted of domiciliary visitation now refuse to give this real obligation to the public and compel their patients who are too ill to visit the office, to go to the hospital. Whatever excuse may be given for this disregard for the comfort, welfare and financial condition of these patients, one is obliged to conclude that it is due really to selfishness and laziness in the desire to escape the hardships experienced by a real family practice; the best and most valuable service a physician may give."

IT is evident that the medical profession at large is beginning to appreciate the dangers that threaten in consequence of the attitude of some of the leaders who are advocating or supporting measures that tend to socialize medicine. What we have had to say concerning the Michigan situation seems to have struck a responsive chord in many states, and it is well that a general uprising in the profession for the defense of inalienable rights and privileges should occur. As indicating the trend of affairs we publish, as requested, a circular being sent out by the medical advisory committee of the Ohio State Medical Association, which reads as follows:

MY DEAR SECRETARY:

As the fate of the Practice of Medicine is at stake, this plea is being sent to every County Medical Society in the United States. Kindly submit it at once to your society for consideration and action.

To Members of the Medical Profession:

The Public and Profession are being sold out to—

(1) Foundation control of "full time" medical education.

(2) Lay board domination and the "closed shop" hospital.

(3) Socialized state medicine, subsidized community health centers, and hospitals under political or university control.

(4) Legislative dictation of therapy and fees.

(5) Demoralization of medical standards by the expansion of cults.

(6) Exploitation of the specialties by lay technicians.

These menacing movements will succeed unless they are combated by a powerful and united opposition. Your so-called leaders are either openly fostering these destructive forces, or more subtly giving them full fling by a camouflaged neutrality.

The American Medical Association belongs to you and you are entitled to have it effectively protect your vital interests. Let your action on this nation-wide referendum carry your mandate.

In the present crisis it is up to every County Society to instruct all Delegates to the A. M. A. meeting at St. Louis, Mo., May 22-26, 1922, to vote for—

(A) A change of policy and leadership in the A. M. A. pledged to immediate abolition of the evils mentioned, and constructive protection of medical interests.

(B) The repeal of multiple representation and plural voting privilege by Section Delegates.

(C) The election of Trustees for a period of two years; five Trustees to be elected one year, and four the next, to prevent the Trustees from perpetuating oligarchical rule.

Unless there is a drastic change in the policy and leadership of the A. M. A. the public and profession at large will continue to be misled and misrepresented in the solution of the most pressing problems affecting public welfare and the practice of medicine.

The members of the Scientific Sections are already represented by the Delegates of their respective State Societies, and the voting of Section Delegates is multiple representation, and as such undemocratic and unfair. Unless this plural voting privilege is repealed, the 15 Section Delegates will continue to negative and outvote the Delegates of 15 State Societies having only one Delegate each.

At present three of the nine A. M. A. Trustees are elected each year for a period of three years. There is a proposal before the House of Delegates, introduced at the Boston meeting (1921) to reduce the number of Trustees to seven and have the term of office seven years. Unless the proposed election of Trustees for seven years is nipped in the bud, the A. M. A. will be relegated to "gang rule" for all time to come.

At the Boston meeting of the A. M. A. (1921) those representing the rank and file of the profession lacked only 7 votes of being in control of the House of Delegates, and would have been able to initiate

a policy of public and medical protection, if they had not been outvoted by the Section Delegates. In this connection the following editorial note of warning is of pertinent interest:

* * * "For the benefit of the large number of State Journals that exchange with us, we desire to call attention to the necessity of determining where the Delegates to the A. M. A. stand on many questions of vital interest to the welfare of the medical profession at large. We have had examples of what some of the leaders in the profession would do to us if they have their way. It is time to know something about the attitude of those whom we send to represent us at the great parent organization, which supposedly represents the voice of a very large majority of the medical men in this country. The trouble of it is we sometimes are betrayed, and if necessary, in order to have our wishes respected, our Delegates ought to go instructed." —(JOURNAL INDIANA STATE MEDICAL ASSOCIATION, November, 1921.)

This warning is all the more necessary since the Board of Trustees, at the Boston meeting (1921), reported that they had under consideration the advisability of the A. M. A. paying the expenses of the A. M. A. delegates. This simply means further subsidizing of the Delegates to control their votes and to thwart the interests of the rank and file. Each State Society that values representation by its own Delegates must take action against this political maneuver.

This is your opportunity of putting your power of attorney into the keeping of only such Delegates to the St. Louis meeting who will openly avow their stand on all vital matters, who will fight your battles and to whom your interests will be a sacred trust.

Self-protection is the first law of life. Act now!

Fraternally yours,
MEDICAL ADVISORY COMMITTEE,
(Signed) F. H. McMechan, M.D., Secretary.

DEATHS

R. B. PETRO, M.D., died at Franklin, Indiana, Friday, December 2, at the age of 78 years.

HARRY S. TONER, M.D., formerly practicing physician of Shelbyville, died November 19 at his home in Austin, Texas.

DAVID H. HAROLD, M.D., died November 30, 1921, at the home of his daughter in Westfield. Dr. Harold graduated from the Physio-Medical College of Indiana, Indianapolis, in 1889.

J. W. ARNOLD, M.D., of Columbus, died December 26, 1921, at the age of sixty-nine years. Dr. Arnold graduated from the Central College of Physicians and Surgeons of Indianapolis in 1885.

WILLIAM C. PROUGH, M.D., of Goodland, 46 years of age, died Tuesday, December 6, at the state asylum at Richmond, where he had been taken last May for treatment of a mental disorder.

CHARLES A. MCCLURE, M.D., died at his home in Eminence, December 28, 1921. Dr. McClure graduated from the Medical Department of the University of Nashville in 1899. He was 62 years old.

CHARLES WESLEY GORDON, M.D., died November 21, 1921, at his home in Fort Wayne, at the age of 69 years. Dr. Gordon graduated from the Fort Wayne Medical College in 1877 and from the Rush Medical College of Chicago in 1880.

SAMUEL R. WHITE, M.D., died at his home in Laud, November 28, 1921, at the age of 63 years. Dr. White graduated from the Fort Wayne Medical College in 1886 and was a member of the Whitley County Medical Society, the Indiana State Medical Association and the American Medical Association.

GREENLY V. WOOLLEN, M.D., age 81 years, died December 10 at his home in Indianapolis. Dr. Woollen was born in Marion county June 24, 1840, and graduated from the Bellevue Hospital Medical College in 1865. He was one of the founders of the Indiana State Medical Association, and served as its secretary from 1865 to 1875; served as president of the Indianapolis Medical Society; held the chair of professor of rhinology and laryngology in the old Central College of Physicians and Surgeons, Indianapolis; for several years was superintendent of the City Hospital, and served as physician to that hospital for 25 years. Since retiring from the active practice of medicine 15 years ago Dr. Woollen has been the medical director of the American Central Life Insurance Company. He was a fellow of the American Medical Association.

ALBERT CARL KIMBERLIN, M.D., Indianapolis, died December 14 as the result of a shooting accident while on a hunting trip. Dr. Kimberlin was born at Fisher's Station, 12 miles north of Indianapolis, January 21, 1863. He graduated from the Indiana Medical College, Indianapolis, in 1888, and served one year's internship at the City Hospital at Indianapolis, later becoming connected with the city dispensary and other Indianapolis hospitals. For several years Dr. Kimberlin has held the chair of Clinical Professor of Medicine in the Indiana University School of Medicine, and has been an active worker in the Indianapolis Medical Society and the Indiana State Medical Association, having served as both secretary and president of his county medical society, and as president of the State Association in 1913-1914. In addition to the above he was a member of the

Indianapolis City Board of Health for several years, member of the House of Delegates of the American Medical Association, and on the clinical staff of both the City and Methodist Hospitals. For a number of years his practice was devoted exclusively to internal medicine, and particularly cardio-vascular diseases, in which subject he was considered an authority throughout the country. The untimely death at the age of 58 years is deeply felt by the medical profession of this state, as he was loved and honored by all who knew him.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in *The Journal of the Indiana State Medical Association*. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

DR. GEORGE R. DANIELS has been elected mayor of Marion.

DR. M. F. HUNN has located in Elkhart, for the practice of medicine.

DR. SCOTT EDWARDS, of Greenfield, has gone to California for his health.

DR. RALPH BRUNER has located at Sellersburg for the practice of medicine.

DR. M. L. CURTNER has been appointed county physician for Knox County.

DR. J. W. MORR, of Albion, has taken up the practice of medicine in that city.

DR. R. R. COBLE has been made superintendent of the City Dispensary of Indianapolis.

MISS JEANETTE NELIGH has been made superintendent of the Marshall County Hospital.

DR. V. G. BLACK, formerly of Fishers, has taken up the practice of medicine in Noblesville.

DR. CLEON NAFE has been made assistant superintendent of the City Hospital at Indianapolis.

MISS LULU SUMMERS has been made superintendent of the Wells County Hospital at Bluffton.

DR. W. P. LAUE has returned to Gary for the practice of medicine after an absence of several months.

DR. CLINTON G. BECKETT, of Attica, was married on Christmas day to Miss Flo Hildebrand, of the same city.

DRS. W. D. GATCH and J. D. GARRETT have resigned from the board of public health and charities of Indianapolis.

DR. MILES F. PORTER, of Fort Wayne, was elected president of the Western Surgical Association at the recent annual meeting.

DR. PHILIP BOWSER has moved to Goshen, where he will take up the practice of medicine in partnership with his uncle, Dr. Irvin J. Becknell.

DR. C. S. WOODS, superintendent of the Methodist Hospital of Indianapolis, left December 10 for Colorado Springs, Colorado, on a leave of absence.

DR. L. M. REAGAN, formerly of Tipton, has located at Kokomo, with offices in the Darby Building, for the practice of medicine and surgery.

DR. S. M. COTTON, of Goldsmith, was elected secretary of Tipton County to take the place of Dr. L. M. Reagan, who has removed to Kokomo.

DRS. H. W. FITZPATRICK, MERLE HOPPENRATH and C. C. COTTON have been made members of the city board of health of Elwood for 1922.

DR. HERMAN G. MORGAN has been reappointed secretary of the city board of health of Indianapolis under the administration of Mayor Shank.

DRS. MAURICE LOHMAN and ERIC CRULL, of Fort Wayne, have returned from the East, where they attended the meeting of the United States Public Health Service.

THE Peru Chamber of Commerce has set aside $2,000 as the beginning of a fund to be used in the erection of a new building for the Miami County Hospital.

A BUILDING permit has been issued for the erection of a new south wing of St. Anthony's Hospital at Terre Haute. It is estimated that the addition will cost $75,000.

THE Jackson County Medical Society held a meeting Thursday, December 1, at the home of Dr. Gillespie, Seymour, Indiana. A paper was presented concerning infections from the teeth and gums.

AT the December 13 meeting of the Vigo County Medical Society the following officers were elected: Dr. A. F. Knoefel, president; Dr. C. M. Depuy, vice-president; Dr. A. M. Mitchell, secretary and treasurer.

DR. VIRGIL H. MOON presented the third of his series of lectures on "The Anatomy, Physiology and Pathology of the Blood and Circulatory System" before the Tipton County Medical Society at Tipton, December 5.

THE Cass County Medical Society held its regular meeting December 15 and elected the following officers for 1922: Dr. F. W. Terflinger, president; Dr. W. W. Holmes, vice-president; Dr. G. D. Miller, secretary-treasurer.

THE Adams County Medical Society held a meeting at Decatur, December 9, and elected the following officers for 1922: President, Dr. H. F. Costello; vice-president, Dr. J. S. Boyers; secretary and treasurer, Dr. Clarence P. Hinchman.

ONE hundred forty nurses passed the registration examinations at Indianapolis. There were one hundred forty-nine applicants. Miss Mildred A. Chaffee, of St. Anthony's Hospital, Terre Haute, headed the list with a percentage of 98.

DR. CHARLES A. BARNHILL, of Indianapolis, who makes a specialty of oral surgery, extraction of teeth and x-ray of head and teeth, announces the removal of his offices from the Hume-Mansur Building to 536-540 Bankers Trust Building.

DR. EUGENE L. BULSON, of Fort Wayne, left January 6 for Philadelphia to take a special course in bronchoscopy and esophagoscopy under Dr. Chevalier Jackson. He also will do some special postgraduate work on the eye while in the East.

AT the regular meeting of the Knox County Medical Society, held Tuesday, December 13, the following officers were elected to service in 1922: Dr. Charles S. Bryan, president; Dr. J. W. Trueblood, vice-president; Dr. D. H. Richards, secretary-treasurer.

THE following officers for the Grant County Medical Society have been elected for the coming year: President, Dr. Harry Williamson; vice-president, Dr. F. A. Priest; secretary-treasurer, Dr. B. C. Dale; censors, Drs. V. V. Cameron and M. F. Baldwin.

THE Randolph County Medical Society held a meeting Monday, December 12. A paper was presented by Dr. Reid, and the following officers were elected for the new year: Dr. C. L. Botkin, president; Dr. C. E. Milligan, vice-president; Dr. J. I. Robison, secretary and treasurer.

THE following officers were elected by the Goshen Medical Society at their regular meeting on December 23: President, Dr. L. H. Simmons; vice-president, Dr. H. W. Eby; secretary, Dr. H. E. Vander Bogart; treasurer, Dr. D. L. Miller; librarian, Dr. E. E. Ash; censor, Dr. I. J. Becknell.

THE Noble County Medical Society held a meeting at Albion, December 13, and the following officers were elected: Dr. A. C. Seymour, president; Dr. Lane, vice-president; and Dr. C. E. Munk, secretary and treasurer. A paper was presented on the subject "Pneumonia."

THE Clinton County Medical Society held a meeting at the home of Dr. A. G. Chittick, December 1, and the following officers were elected for 1922: Dr. W. C. Mount of Kirklin, president; Dr. J. A. Van Kirk, vice-president, and Dr. L. L. Harding, secretary-treasurer.

THE Wabash County Medical Society held its regular meeting, Thursday, December 15, and elected the following officers for 1922: President, Dr. N. T. Hale; vice-president, Dr. Browne; secretary and treasurer, Dr. Cripe. A paper was presented by Dr. M. F. Jordan on "Salpingitis".

THE Fulton County Medical Society held its annual meeting Friday, December 2, and the following officers were elected to serve during 1922: Dr. B. F. Overmeyer, president; Dr. A. E. Stinson, secretary-treasurer. Drs. King, Brown and Shafer were appointed to act as the program committee.

THE Howard County Medical Society held a meeting December 2, and the following doctors were elected as officers of the society for 1922: Dr. E. N. Bennett, president; Dr. F. S. Cuthbert, vice-president; Dr. W. R. Morrison, secretary-treasurer. A paper was presented by Dr. R. P. Schuler on "Four-Hour Feeding for Infants".

AT a meeting of the Indiana State Sanitorium Association, held at the Irene Byron Hospital, Wednesday, December 7, the following officers were chosen to head the Association: Dr. Alfred Henry of Indianapolis, president;

Dr. Gardner Johnson, of Evansville, vice-president; Dr. Eric Crull, of Fort Wayne, secretary-treasurer.

ATTORNEY GENERAL U. S. LESH declares that chiropractors cannot give certificates of physical disability which will excuse children from attending school under the provisions of the compulsory school attendance law. The attorney general declares that chiropractors are not physicians in good standing in this state and therefore chiropractors' certificates are not sufficient.

THE first examination of the National Board of Medical Examiners, under the new plan, will be held as follows: Part I, February 15, 16 and 17, 1922, inclusive; Part II, February 20 and 21, 1922, inclusive. Application blanks and circulars of information may be had by writing to the Secretary, Dr. J. S. Rodman, 1310 Medical Arts Building, Philadelphia, Pa.

DR. JOHN MCCOY, a native of Spencer county, died December 20 in the hospital at the Soldiers' Home, Pasadena, California. Dr. McCoy was born in 1835, graduated in medicine from the Medical Department of the University of Michigan and served as surgeon with the 130th Indiana Infantry in the Civil War. Dr. McCoy had lived in Pasadena for 36 years.

THE Kosciusko County Medical Society met December 27 with a banquet at the Hotel Hays. Reports of the year's work were read, and officers for the ensuing year elected as follows: President, Dr. C. C. DuBois, Warsaw; vice-president, Dr. Paul A. Garber, Sidney; secretary-treasurer, Dr. O. H. Richer, Warsaw; delegate to State Convention, Dr. J. F. Young, Milford.

THE physicians and surgeons of Alexandria held a meeting at the Alexandria Hospital, December 1, and the following staff was elected: President, Dr. A. E. Otto; secretary-treasurer, Dr. H. C. Runyan; directors, Drs. J. E. Hall, J. J. Gibson, C. D. Schurtz, F. G. Keller and Mr. Harry Adams. Mrs. L. F. Schmauss was made managing director and superintendent of the hospital.

THE U. S. Public Health Service has felt it necessary to prevent the too optimistic and extravagant claims recently appearing in the newspapers in regard to the curative effects of chaulmoogra oil derivatives in the treatment of leprosy. While the use of the oil and its derivatives has resulted in a considerable number of apparent cures, it is as yet too soon to tell whether these cures will be permanent.

THE Kokomo Physicians' Telephone Exchange was opened Monday, December 12. The physicians' telephone exchange is a recent idea and is spreading throughout many cities. By this plan the telephone operators of this exchange will know just where every doctor is, whether he can be reached promptly or not and whether it will be advisable to call in another physician, in case of an emergency. The plan is proving very popular.

AT the regular meeting of the Delaware-Blackford County Medical Society held December 2, the following officers were elected: Dr. W. C. Moore, president; Dr. H. S. Buckles, vice-president; Dr. C. S. Bock, secretary-treasurer. A paper was presented by Dr. Byrl Kirklin on "Diagnosis of Bone Diseases". Plans were made for the entertainment of the Indiana State Medical Association, which will hold its annual convention at Muncie this year.

DR. W. D. CALVIN, of Fort Wayne, has announced the limiting of his practice to dermatology and genito-urinary diseases. Dr. Calvin formerly taught this subject in the old Fort Wayne Medical College, and was assigned this special work while in military service during the World War. He recently has completed special postgraduate work in Washington University, and is now limiting his practice, with offices at 312 West Wayne Street, Fort Wayne, hours 10 to 4.

THE McIntosh Battery and Optical Company of Chicago, one of the oldest and best-known x-ray, electro-medical and physical therapy apparatus manufacturers in the United States, has been reorganized with an increase of capital stock under the name of the McIntosh Electrical Corporation. Coincidental with this enlargement the Company has established distributing agencies in almost every state in the United States in the hands of local men. Mr. A. W. Zimmerman, of the Zimmerman Supply Company, 1331 Calhoun Street, Fort Wayne, has the agency for Indiana.

AT the annual meeting of the Indianapolis Medical Society, held January 3 at the Indiana Dental College, the following officers were elected for the ensuing year: President, Dr. Lafayette Page; first vice-president, Dr. George S. Row; second vice-president, Dr. Harry K. Langdon; secretary-treasurer, Dr. William A. Doeppers; librarian, Dr. Frank B. Wynn; members of the judicial council, for three-year terms, Dr. Ross Ottinger and Dr. Bernard Erdman; delegates to the State Association, Dr. E. F. Kiser, Dr. A. L. Marshall, Dr. J. A. MacDonald, Dr. C. H. McCaskey, Dr. John Sluss, and Dr. John Carmack.

THE Public Health Institute to be held at Indianapolis, February 13 to 18, inclusive, under the auspices of the U. S. Public Health Service, the Indiana University School of Medicine, and the State Board of Health, promises to be of unusual interest and value to the medical profession of the state. The lectures will be held in the auditorium of the Lincoln Hotel, Washington and Illinois streets, and will begin at 1 p. m., Monday, February 13, and close at 12 M., Saturday, February 18. In addition to the lecture course there will be a series of clinics on tuberculosis, and venereal diseases, an intensive laboratory course, and a Woman's Conference. There will be no fees or charges of any kind whatsoever. Full particulars concerning the program and other details may be secured from Dr. W. F. King, Director of the Institute, care of the State Board of Health, Indianapolis.

DURING December the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: The Abbott Laboratories: Neocinchophen-Abbott. Powers-Weightman-Rosengarten Co.; Mercury and Potassium Iodide-P. W. R. Schimmel & Co.: Oil of Cypress-Schimmel & Co. E. R. Squibb & Sons: Liquid Petrolatum-Squibb; Food Allergens-Squibb; Pollen Protein Allergens-Squibb; Animal Epidermal Extract Allergens-Squibb; Bacterial Allergens-Squibb. Winthrop Chemical Co.: Chaulmestrol. Nonproprietary Article: Chaulmoogra Oil.

CHANGE OF AGENCY: CRESATIN.—The Council has directed that the description of Cresatin (New and Nonofficial Remedies, 1921, p. 94) be revised to show that the name has been changed to Cresatin—Dr. N. Sulzberge, and that it is manufactured by the Intravenous Product Company of America, Inc.

THE GOLD CURE

An unfortunate man, possessed of a comfortable competency, evidenced various eccentricities, and so his loving relatives tenderly escorted him to a famous neurologist. The latter viewed the patient from different points of the compass, and in due course passed him on to a psychopathologist. This polysyllabic expert subjected him to an exhaustive analysis and presently shucked him off onto a psychiatrist. The latter had hardly more than begun his investigation when the patient lost the most of his money. Thereat his kin turned him loose, declaring that they had no more time to waste on a darned old crank. And he fell into the hands of a shabby plug of an unknown general practitioner, who gave him a few doses of bitter stuff and cured him for a dollar and sixty cents.—*Country Gentleman.*

FORT WAYNE MEDICAL SOCIETY

The annual meeting and dinner of the Fort Wayne Medical Society was held Tuesday evening, December 20, at the Chamber of Commerce, Fort Wayne. Dr. E. M. Van Buskirk, president, presided over the following program: "Present Day Cardiology," Dr. George Hermann, Ann Arbor; "Methodism vs. Medicine" or "Can a Doctor Be a Christian?", Dr. Kent K. Wheelock; "The Medical Mystery," by "Mustapha Ali Ben Haggin". The program was interspersed with music.

The following officers were elected for the coming year: President, Dr. A. L. Schneider; secretary, Dr. Miles F. Porter, Jr. (re-elected); treasurer, Dr. E. E. Morgan (re-elected).

INDIANAPOLIS MEDICAL SOCIETY

Meeting of Dec. 15, 1921

At this Kimberlin memorial meeting addresses touching upon the life and work of Dr. A. C. Kimberlin were presented. Dr. Frank B. Wynn gave the following:

"Upon this occasion I am weighed down not only by grief at the loss of a dear friend but by the consciousness that my words must express the depth of feeling which stirs your hearts. A nobleman from our ranks has been cut down, before his allotted time. The tragedy of his going appals us and its suddenness reminds us of the uncertainties of life.

"At this time whilst our memories hark back to the intimacy of our mingling with him—his devotion to this Society; his frequent and enlightening participation in its proceedings; his exhaustive and informing articles upon medical subjects; his fine and satisfying grasp of clinical medicine; the wisdom of his counsel, the goodness of his heart, the gentleness of his spirit, the sincerity of his friendship and the greatness of his soul—will all be cherished by us as a precious heritage.

"Resolutions are formal and cold; my words wholly inadequate to express our affection and appreciation of him who was of us, and for us; a leader whom we could follow, safely, confident that he would show the way; a physician who exalted the scientific, the clinical and spiritual ideals of medicine, a man to the core, who sought ever to be his brother's keeper; dutiful in his obligations to the community; true to his own flesh and blood. 'We shall not soon look upon his like again.'

"It were perhaps better at this time not to particularize upon incidents of his life; for where would the narrative end? We would emulate his life and example. This we may do better if, instead of many incidents, we stress two of the outstanding traits of his career. It will be remembered that at the last feast of the Great Physician, there sat amongst the twelve Apostles, Luke the beloved physician. He utters these stately words: 'No man having put his

hand to the plough, and looking back, is fit for the kingdom of God.' And was this not always true of our beloved colleague? Steadfastness (I like the word), unswerving steadfastness characterized his whole life. Even in his country-boyhood life, intelligent, affectionate parents would have had him follow in their footsteps on the farm, but his eyes were fixed upon the practice of medicine—that was the goal for which his heart yearned, and never did he deviate from that resolution. With the same determined enthusiasm he studied medicine in the Indiana Medical College, winning distinction as a thorough student; during his internship at the City Hospital, his diligence and thoroughness in clinical work, won a devoted and life-long friendship with every member of the Staff; or was it as teacher of anatomy, or Professor of Clincial Medicine in the School of Medicine, his thoroughness and eagerness to know the whole truth, gained the confidence and admiration of students.

"He was big enough to recognize and deplore his own shortcomings. It was with him a matter of extreme regret that he had not received a collegiate education. Here again his steadfastness was shown in his struggles to realize higher ideals. For two years after his graduation he took systematic private tutoring in cultural subjects. This training was apparent in his writing and in his discussions of medical papers. The Professor of Medicine in one of the oldest medical colleges in the West once observed to me concerning a discussion Dr. Kimberlin had given in a national meeting, that it was one of the finest he ever heard. His fluency, grasp of the subject, orderly arrangement of his ideas always made his friends feel at ease and proud of his efforts.

"His career as a general practitioner was triumphal, not merely in the matter of business volume, but in the larger sense, that the high quality of professional services which he rendered, merited and received devoted approval. He was an ideal family doctor. Feeling that the stress of his multiplying responsibilities was threatening inroads upon his health he resolved upon devoting his energies to a more limited field, by his studies and writing seeking to justify a claim for ability as a consultant in both the professional and public mind. Here again came into play his ceaseless industry and unwavering steadfastness to medical ideals. Whilst in his work as an internist he brought the tremendous aid of his vast clinical experience, he never allowed this to befog his vision for other diagnostic helps. He was always eager to collaborate. The large consultative practice which he did bore eloquent testimony to his ability, the wisdom of his counsel, and the enlightening and helpful attitude which he always showed toward his confreres. His election to the Presidency of this Society and the State Medical Society, was an expression of the esteem and affection in which he was held by the profession throughout the State.

"An incident occurring the past summer will illustrate his ability and gift to handle himself creditably on public occasions. At a medical banquet of two hundred and fifty the speaker of the evening was one of the most distinguished surgeons of the whole country. Since the meeting was held in a smaller Indiana city he did not prepare for the occasion. Arriving late he looked in upon this fine assemblage of men and exclaimed 'Why, I was not counting upon an occasion like this. I am not prepared.' His audience soon found that his statement was correct, for he rambled most disconnectedly and disappointingly. The presiding officer noting the presence of Dr. Kimberlin in the back of the hall, suggested that it might be appropriate to hear from an internist on the subject which the surgeon had presented. Dr. Kimberlin never in his life appeared to better advantage. In his clear, fluent, and incisive manner he talked for twenty minutes, commanding the rapt attention of those present. The unanimous opinion of all present was that it had been a great evening, but that the outstanding address had been Kimberlin's.

"In the Book of Books we read 'The grass withereth, the flower fadeth.' And whilst Isaiah thus wrote figuratively of life, in the case of our colleague I should prefer to think of him as a tree. Indeed I should liken him unto the 'Old Oak Tree' under which I played as a country lad—a great white oak towering 200 feet into the air, five feet in diameter, standing there alone, strangely left from its primeval brothers. Like our dear friend who has gone, how steadfast it had been through the two centuries of its existence. It stood as a sentinel to direct travelers for miles around. Benevolence it showed to the hornets' nest which hung from a bough; protection to the chipmunk which hid itself securely under the deep roots; kindliness to the trumpet vine which clung about its trunk; refuge to the distracted quail which secluded itself among the leaves; comfort to the harvest laborers who rested in its shade at noontime; merriment it gave in the swing which hung from its great arm; patience it taught me, for had I not seen it at its job my whole life through; courage it taught me, for had I not seen it swayed in the surging blasts of winter. The old tree had taught me all the worth-while attributes of life—that the greatest thing is to live to the full of one's abilities, to love and to serve. Figuratively speaking A. C. Kimberlin was an 'Old Oak Tree'. And like this monster of the primeval forest he came to a tragic end. Lightning claimed the one, tearing it into ten thousand splinters, as did accident fell the other.

"The Creator has claimed them both. They are not dead. It was worth while to have known this man. Let us think on his life."

Dr. W. N. Wishard, who was prevented from attending the meeting, sent a communication which was as follows:

Indianapolis, December 15, 1921.

Officers and Members of the Indianapolis Medical Society, Indianapolis, Ind.

Gentlemen:

I regret very much that a temporary illness will prevent my being with you tonight when you meet to do honor to the memory of one who has done so much for this organization.

I first met Dr. Kimberlin in 1886 when he was attending the old Medical College of Indiana. Our acquaintance was deepened and strengthened by the fact that I was his preceptor during his medical school work.

The characteristics which were so marked in his student days have become more noticeable as the years have passed. I recall very vividly today his appearance and the boyish frankness, kindliness and eagerness for work when he first came to the City Hospital to see me during the latter part of my administration as Superintendent. He used to come out to the hospital on his velocipede, one of the wheels of which was very large and the other quite small, but which maintained sufficient speed to enable him to attend to his medical school work and yet spend considerable time at the hospital.

Every member of the medical school faculty and every one in any official or professional capacity at the City Hospital dearly loved "Allee Kimberlin" as he was affectionately called by all. The unusual candor and sincere sympathy and interest in his patients that marked his early career was accompanied by

an eager scientific interest and effort in their behalf. He has always been a student and a wonderfully efficient and industrious one.

I recall his coming to my office one day not long after he had left the hospital and stating that he had been keenly conscious of his general educational deficiencies at the time he entered the medical school. He asked me to suggest a teacher in history and literature, which I was glad to do, and he pursued his private studies in this direction for two or three years, until his practice became large enough to occupy all his time.

He held at the time of his death a very enviable position. To his professional confreres, to his students and to his patients and to the public hospitals of Indianapolis he has been a wise counselor and loyal friend to whom we have all turned with hope and confidence. I know of no one who can quite take his place. We are all richer and better for having known him.

As a consultant in internal medicine the profession of Indiana and adjoining states will feel his loss almost as keenly as we do. I never knew a physician to call him in consultation or meet him for the first time who did not entertain for him an unusual quality of respect and confidence. Most of them felt that he was already an old friend and he became a fast friend of the great majority.

He was tolerant of the opinions of others and yet clear and firm in his own views. I was early impressed with his perfect candor when a medical student, and later as a young practitioner, and in more maturer years I have never known him to fail to frankly declare himself a sincere believer in the Christian religion. Neither have I ever known him to criticize the religious views of others.

As a Christian gentleman, an unusually wise and efficient physician, as a personal friend and a rare type of citizen, he stood to those of us who knew him intimately somewhat in a class alone, or at least as one who blended the elements of goodness, gentleness, greatness and love in a rare way.

Personally, I cannot trust myself to speak of what his passing means to me and can only say

"Dear, dear friend, hail and farewell."

DECATUR COUNTY

At a regular meeting of the Decatur County Medical Society, held December 19, 1921, the memorial committee presented the following resolutions concerning the death of Dr. A. C. Kimberlin, of Indianapolis:

Greensburg, Indiana, Dec. 19, 1921.

The memorial committee of the Decatur County Medical Society on the death of Dr. A. C. Kimberlin, presents the following report.

Words fail adequately to express the regret and sorrow felt by the Decatur County Medical Society over the tragic and untimely death of Dr. A. C. Kimberlin.

Dr. Kimberlin was frequently called to Greensburg and vicinity as a consultant and had the respect and confidence of members of this society, as well as the laity. He was ever courteous, kind and sincere, leaving a ray of hope and comfort. Dr. Kimberlin possessed an unusual degree of skill, and was ever willing and ready to use such skill for the relief of suffering humanity. We feel that his place cannot be filled, but we submit to the will of the Great Physician who doeth all things well.

Resolved, that the society extend its heartfelt sympathy to the widow of Dr. Kimberlin and relatives, with a prayer that an all wise Providence comfort, protect and care for them in this their great affliction.

Resolved, that a copy of these resolutions be sent to the widow, The Journal of the Indiana State Medical Association, and that they be spread on the records of our local society.

D. E. DOUGLAS.
I. M. SANDERS.
P. C. BENTLE.

PUBLIC HEALTH INSTITUTE AT INDIANAPOLIS, FEBRUARY 13-18, 1922.

The U. S. Public Health Service, in co-operation with the Indiana State Board of Health and the Indiana University School of Medicine, has arranged for a Public Health Institute to be held in Indianapolis for the entire week, beginning February 13, 1922. This institute is one of a series of such institutes to be held in twenty-four of the larger cities of the United States in order that the advantages of such an institute may be brought within reasonable reach of every section of the country. These institutes will be open to every person who may care to attend, without charge, and will furnish a splendid opportunity for physicians, not only to "brush up" and broaden intellectually, but also to renew and extend acquaintances throughout the state and meet some of the good men from other states. Health officers, nurses, social welfare workers and all others interested will have advantage of a short, intensive course covering the various phases of public health and social welfare work under the leadership of experts in every line.

For the Indianapolis Institute the lecturers and their subjects will be as follows: Dr. Wm. C. White, of Pittsburgh, on "Tuberculosis"; Dr. Rachael S. Yarros, of Chicago, on "The Delinquent"; Dr. Frederick Green, of the American Medical Association, on "Health Education"; Dr. William N. Wishard, of the Indiana University School of Medicine, on "Gonorrhea"; Dr. Frank W. Cregor, of the Indiana University School of Medicine, on "Syphilis"; Miss Jessie Binford, of the Interdepartmental Social Hygiene Board, Washington, on "Protective Social Work"; Dr. A. T. McCormack, State Health Commissioner, of Kentucky, on "Administrative Problems in Public Health"; Dr. Wm. A. Evans, of Chicago Tribune, on "The General Communicable Diseases"; Dr. Charles P. Emerson, Dean of the Indiana University School of Medicine, and Dr. Frank S. Hutchens, Indiana University School of Medicine, on "Mental Hygiene."

In addition to the above there will be lectures on child hygiene, nutrition in health and disease, sanitary engineering, industrial hygiene, etc. Dr. Alfred Henry, of the Indiana University School of Medicine, has arranged a series of tuberculosis clinics, at which the modern methods of examination and early diagnosis will be demonstrated. A series of venereal disease clinics will be given in connection with the Indianapolis Venereal Disease clinic. Dr. Virgil H. Moon, bacteriologist for the Indiana University School of Medicine, and Dr. William Shimer, Superintendent of the Laboratory of the State Board of Health, have arranged an intensive course in serology, bacteriology and microscopy for the benefit of physicians and others interested. In addition to the regular daily program, and program of clinic and laboratory demonstrations, there will be a public meeting each evening. Dr. Evans, Dr. Emerson, Dr. Green, and others will address these public meetings on subjects of general interest to the public.

The meetings of the Institute will be held in the Auditorium of the Lincoln Hotel, which has a seating capacity of 700 with rooms for committee and group meetings and is admirably adapted to the

purposes of the Institute. It is believed that the program of this Institute should appeal to health officers, physicians, social workers, nurses and all others interested in public health and public welfare, not only in the state of Indiana, but in surrounding states as well. The interest already shown indicates a large attendance at the Institute. Dr. W. F. King, Assistant Secretary State Board of Health, is Director of the Institute, and will be pleased to give personal attention to any inquiry concerning the Institute.

MUNCIE ACADEMY OF MEDICINE

At a regular meeting of the Muncie Academy of Medicine the following memorial resolutions concerning the death of Dr. A. C. Kimberlin, of Indianapolis, were adopted:

In the drama of life the physician plays a leading role. From the dawn to the eventide the issues of life are his care and concern. To him is committed the holy rite of lifting the veil on life at birth, and he is there when the curtain falls on the closing scene. His are the first hands to touch the new born and the last to minister to the stricken and dying.

To be highly endowed by nature, well trained, fully equipped and wholly dedicated to such a mission is to be ordained as a coworker with God in the conservation of life and the promotion of human health and happiness. It is at once a mission and a ministry which should inspire the highest motives and the fullest consecration to service. He most truly lives who best loves and serves his fellowman.

Thus lived, thus labored and in high degree attained, did the subject of this memorial, our friend, comrade and coworker, Dr. Albert C. Kimberlin. He, whom we all knew and loved, and whom we mourn tonight, was so much a part of us he seemed to belong to us. For many years his contributions to our medical organizations had been frequent and inspiring. In his personal contact, as in his professional relations, he happily exemplified the high standards and ideals he so ably advanced as teacher and lecturer. Therefore, be it

Resolved by the Muncie Academy of Medicine, in regular meeting assembled, that in this expression of sorrow in the tragic and untimely death of Dr. Kimberlin, we voice a sense of personal loss shared by a vast throng of friends and coworkers throughout the state.

Resolved, that in his death at the very zenith of his powers, scientific medical teaching has lost an earnest, fluent and clear thinking exponent, and the practicing physician an able counselor. And be it

Resolved, that to those with whom he mingled in daily contact or frequent association,—the church, the fraternal and benevolent organizations with which he fellowshipped and to whose efficiency he so ably contributed, we extend that sympathy which finds comradeship in sorrow. And be it further

Resolved, that to his grief stricken home, to the members of his household, whose loss is too personal and whose sorrow is too sacred for us to share, we offer the benediction and consolation of the memory of a noble life, nobly lived, to full fruition and "crowned with glory and honor." And be it finally

Resolved, that a copy of this memorial be furnished his family and to the various institutions and organizations of which he was a member and to the various medical periodicals for publication, and that it be made a part of the record of the proceedings of this Academy.

W. W. WADSWORTH.
F. G. JACKSON.
WILL C. MOORE,
Committee.

December 15th, 1921.

GRANT COUNTY

The Grant County Medical Society met in regular session at Marion on Tuesday evening, December 20, at which time the annual election of officers was held, with the following results: President, Dr. Harry Williamson; vice-president, Dr. V. V. Cameron; secretary-treasurer, Dr. B. C. Dale.

NETTIE B. POWELL, Sec'y.

KNOX COUNTY

The forty-sixth annual meeting of the Knox County Medical Society was held at the Y. M. C. A., Vincennes, December 13. A banquet was served, following which a 5,000 foot moving picture film of obstetrics and gynecology, by Prof. Werthein and Prof. Weibel, of Vienna, Austria, was shown. Seventy-seven physicians were present, including guests from Knox, Daviess and Sullivan counties, Indiana, and Lawrence and Wabash counties, Illinois.

Officers for the year were elected as follows: President, Dr. Chas. E. Bryan, Vincennes; vice-president, Dr. J. W. Trueblood, Monroe City; secretary-treasurer, Dr. D. H. Richards, Vincennes; censor, Dr. N. E. Beckes, Vincennes.

Adjourned.

D. H. RICHARDS, Secretary.

MONTGOMERY COUNTY

At the meeting of the Montgomery County Medical Society held at Crawfordsville, December 20, the following officers were elected for the ensuing year: President, Dr. William T. Gott, Crawfordsville; vice-president, Dr. T. Z. Ball, Crawfordsville; secretary-treasurer, Dr. B. N. Lingemann, Crawfordsville.

A. L. LOOP, Sec'y.

HAMILTON COUNTY

At the December meeting of the Hamilton County Medical Society the following officers were elected for the coming year: President, Dr. K. C. Hershey; vice-president, Dr. C. R. Elfers; secretary, Dr. W. F. Baker.

After the election Dr. Karl R. Ruddell, of Indianapolis, presented a paper on "Toxic Goitre," dealing with the diagnosis and treatment. An interesting discussion followed the reading of the paper.

W. F. BAKER, Sec'y.

JASPER-NEWTON

The Jasper-Newton County Medical Society announces the following program for the coming year: January—Host, Dr. E. Besser, Remington; subject, "Pathology and Diagnosis of Different Types of Pneumonia," Dr. M. D. Gwin and Dr. W. C. Mathews. February—Host, Dr. C. C. Bassett, Goodland; subject, "Influenza, Colds, Grip, and Similar Infections; Diagnosis and Treatment," Dr. Alfred Ranier and Dr. T. E. Collier. March—Host, Dr. T. E. Collier, Brook; subject. "Muscle and Joint Infections. Acute Rheumatic Fever, Rheumatoid Arthritis; Etiology, Diagnosis, Symptoms and Treatment," Dr. G. D. Larrison, and Dr. C. E. Triplett. April—Host, Dr. E. C. English, Rensselaer; subject, "Cerebral Hemorrhage. Embolism and Thrombosis; Varieties, Symptoms and Treatment," Dr. Frank Kennedy and Dr. E. Besser. May—Host, Dr. M. D. Gwin, Rensselaer; subject, "The Tonsil," Dr. J. G. Kinneman; "Treatment," Dr. I. M. Washburn. June—Host, Dr. Frank Kennedy, Goodland; subject, "Obstetrics; Care of Mother Before Delivery," Dr. G. H. VanKirk; "Method of Delivery," Dr. C. C. Bassett. July—Host, Dr. G. D. Larrison, Brook; subject. "Typhoid Fever." Dr. L. H. Recher; "Colon and Other Infections," Dr. E. C. English. August—Host, Dr. W. C. Mathews, Kentland; subject, "Diabetes, Etiology and Symptoms,"

Dr. F. L. Morehouse; "Treatment," Dr. C. E. Johnson. September—Host, Dr. A. R. Kresler, Rensselaer; subject, "Fractures, Neck of Femur, Colles, and Potts," Dr. E. N. Loy; "Treatment," Dr. H. S. Hewitt. October—Host, Dr. Alfred Ranier, Remington; subject, "Eczemas of Nursing Babies," Dr. E. S. Gibson. "The Tineae, Impetgo Congagiosa," Dr. F. H. Hemphill. November—Host, Dr. I. M. Washburn, Rensselaer; subject, "Diagnosis of Common Infections of Eye," Dr. A. R. Kresler; "Treatment," Dr. J. T. Martin. December—Host, Dr. G. H. Van Kirk, Kentland; subject, "Dyspnoeas," Dr. J. G. Kinneman. Annual election. Officers of this society are, president, Dr. Alfred Ranier and secretary-treasurer, Dr. O. E. Glick.

BENTON COUNTY

The Benton County Medical Society met at the home of Dr. W. H. Taylor, November 8, in regular session, and elected the following officers for 1922: President, O. M. Flack, Boswell; Secretary, J. L. Morehouse, Fowler.

All members were present except three. The society voted to meet bimonthly during the year 1922.

Dr. Mac Gillavry presented a very interesting address on Purpura Hæmorrhagia and Dr. Atkinson reported an interesting method of eliminating diphtheria from schools. Dr. Hubbard reported the birth of an acephalus delivered by Dr. Taylor and himself.

Adjourned. W. H. TAYLOR, Secretary.

TIPPECANOE COUNTY

After a 6:15 p. m. luncheon at the Hotel Lahr, Lafayette, on November 29, Vice-President Ruschli called the regular meeting to order. Minutes of previous meeting read and approved without change.

Dr. Crockett read a paper on "Resumé of Three Clinical Cases from a Diagnostic Standpoint". Cases typical of many that the general practitioner sees so often—robust and healthy appearing people, but complaining of distressing bladder symptoms.

First Case:—Perfect physical appearance; married; two months pregnant. Bladder symptoms: Frequent micturition, tenesmus, pain, bloody urine; no backache. First attack three and one-half years ago. Aggravated at each pregnancy. Cystoscopy negative except three small blebs near trigone, and right ureteral orifice red and spurting red urine, which carried tubercle bacilli, associated with colon bacilli. Pain not dominant symptom of tubercular kidney until bladder is affected; pain in not over thirty-five percent; micturition at night only after bladder involved. Nephrectomy performed and all bladder symptoms better.

Second Case:—Mrs. H. S. Seen first, April, 1921. One child. Physical appearance good, well nourished, pendulous abdomen. Complains of usual distress—bladder symptoms. First attack three years ago, repeated at long intervals; lately very severe. Urine free from blood and pus. Not up at night, as a rule. Pain increases at menstrual period, also when on feet. Cystoscopy revealed no pathology, excepting a little bagging in of bladder in region of right lower quadrant, and few small elevated points in this region. Uterus slightly anteflexed, but not fixed by adhesions. Applied properly fitting abdominal support, and distress relieved.

Third Case:—Well nourished, general physical condition good. Bladder trouble gradually developed from one year ago. Micturition frequent both night and day; pain during passage, and burning after. Never any pus or blood in urine. Tender on deep suprapubic pressure. Married, but no pregnancy. Trouble commenced one year after laparotomy with removal of appendix, and left ovary and tube. External examination of genito-urinary negative. Cystoscopy: Lower left half of bladder, three small irregular ridges with thickening and reddening of subjacent mucosa involving the trigone. Digital palpation through vagina over this area elicited pain or tenderness. Vesicle surface at outlet irregular. Symptoms aggravated at night, but not at time of menstruation,—trigonitis, but the cause not yet determined.

Discussion:—VAN REED: Case of severe chills and fever with symptoms referable to kidney region. Urine from right kidney showed bacilli that were suspicious. Nephrectomy, and tubercle bacilli proven.

Another case, forty-two years old, severe pain coming on suddenly, radiating toward bladder. Relieved by morphine, hypodermatically, followed by passing large quantities of urine.

RUSCHLI:—Case, female aged sixty years. Incontinence; hysterectomy by another surgeon. Cystoscopy revealed nothing. Demonstrated urine was coming out of vagina—ureteral fistula into vagina. Anastomosed ureter into bladder. Successful.

DR. LAIBY: Quoted where teeth and tonsil infections were prone to cause kidney infections. Experiments demonstrated these infections had an affinity for genito-urinary tract. Colon bacilli demonstrated to be only a secondary contamination.

SCHREIBER: Frequently found pendulous abdomen cause of bladder symptoms. Binder relieved.

WESTFALL: Does increase of uric acid in blood have a tendency to produce nephritis?

DR. HUNTER: Blood chemistry may detect beginning nephritis before analysis of urine demonstrates it.

Dr. Crockett in closing stated that every case of persistent urinary symptoms has a source somewhere, if it can be located. Sometimes the most obvious source is overlooked.

Dr. Chenoweth reported a case of recurrent appendicitis; the first occurring ten years previously. Last attack characterized by intense symptoms accompanied by leukopenia—three thousand whites. Hurriedly operated and in two days the leukocytes were ten thousand; made an uneventful recovery.

DR. KEIPER: Often see leukopenia in grave mastoid cases, so cannot rely upon laboratory alone, but have to study all cases from the general symptoms as well.

DR. MCCLELLAND: Had leukopenia in the case of a hand infection, rapidly grew worse and died.

DR. IKENS: Reported three cases of median nerve injuries, two by direct force, and one by penetrating wound. All presenting themselves for treatment some time after injury. Both sensory and motor functions injured. No trophic disturbance in the direct force cases, but in the penetrating wound in which the nerve was severed there was marked trophic disturbance. In the two pressure or force cases, the sensory function returned first, as usual, and the motor is being gradually restored; still under treatment. In the case of the severed nerve, part of the area of distribution was hyperesthetic and part anesthetic. Cut down, and with difficulty found the ends (the distal one being enlarged, cauliflower shaped), and sutured them. No infection and expect good results, but will have to wait six to twelve months yet because results are always slow.

DR. HUNTER, pathologist: The enlarged end of nerve found by Dr. Ikens showed fibrous degeneration.

The following resolution was read by Dr. Keiper and unanimously adopted:

"To the General Public:—The Tippecanoe County Medical Society heartily endorses the Anti-Spitting

Campaign now being propagated by the Tippecanoe County Tuberculosis Association.

Spitting in and on the public highways is a nasty habit, and very dangerous to public health. If you must spit, spit in a paper napkin and then burn it, especially if you have tuberculosis, syphilis, diphtheria, or any other communicable disease.

We also urge the people to buy liberally the Christmas seals offered for sale."

Legislative matters were freely discussed, and it was unanimously voiced that with the beginning of the new year, the legislative committee must be named, and that everyone must do his part by being active early in the campaign, and keeping everlastingly at it.

Members present, twenty-nine. Visitors, one.

Adjourned. WM. M. RESER, Secretary.

ST. JOSEPH COUNTY

The thirty-sixth annual meeting of the St. Joseph County Medical Society was held Wednesday, November 16, at South Bend, in the Auditorium of the Elks' Club. The following program was carried out: "Evaluation of Symptoms in Diagnosis," Albert E. Sterne, Indianapolis; "Reflex Abdominal Disorders," Arthur E. Elliott, Chicago; "Operations on the Gasserian Ganglion, with Report of Cases," John F. Barnhill, Indianapolis; "Conservation of the Patient," Frederick G. Dyas, Chicago. Dinner was served at 6:30 p. m. at the Oliver Hotel, followed by an address on "The Physician and the Public," by Dean Stanley Coulter of Purdue University.

THE TRUTH ABOUT MEDICINES

NEW AND NONOFFICIAL REMEDIES

BROMIPIN 10 PERCENT.—A bromine addition product of sesame oil, containing from 9.8 to 11.2 percent of bromine in organic combination. It acts like the inorganic bromides; but since it yields its bromine more slowly, it is thought to have less tendency to produce brominism. Bromipin 10% is said to be more lasting in its action than the bromides. The dose is 4 Cc. (1 fluidrachm), which may be increased in cases of epilepsy to from 8 to 30 Cc. (2 to 8 fluidrachms). Bromipin 10 percent is a yellow oily liquid, having an oleaginous taste. Merck & Co., New York.—(*Jour. A. M. A.*, Dec. 3, 1921, p. 1819).

AMYLZYME.—An extract containing all of the digestive enzymes of the fresh pancreas of the hog. It has the power to digest starch and protein and to split fats. It is claimed that it is of value in digestive disturbances resulting from a deficiency of pancreatic secretion. Amylzyme is sold only in the form of 2 grain capsules. G. W. Carnrick Co., New York. (*Jour. A. M. A.*, Dec. 10, 1921, p. 1891).

THEOBROMINE-P. W. R.—A brand of theobromine-N. N. R. For a discussion of the actions, uses and dosage of theobromine, see New and Nonofficial Remedies, 1921, p. 362. Powers-Weightman-Rosengarten Company, Philadelphia.—(*Jour. A. M. A.*, Dec. 10, 1921, p. 1891).

POTASSIUM MERCURIC IODIDE.—POTASII HYDRARGYRI IODIDUM.—A complex salt, K_2HgI_4, formed by the interaction of one molecule of mercuric iodide with two molecules of potassium iodide, containing about 25 percent of mercury. Potassium mercuric iodide is used for the same purposes as mercuric iodide, over which it has some advantages because of its solubility. As a germicide, it is effective since it does not coagulate albumin; however, there seems to be no work to show how much the activity is decreased when an excess of potassium iodide is present. As a germicide, potassium mercuric iodide is used in concentrations of from 1:100 to 1:10,000. Solutions of potassium mercuric iodide may be prepared: (1) by dissolving one part by weight of mercuric iodide and one part by weight of potassium iodide in a small amount of water and then diluting to proper strength; (2) by dissolving potassium mercuric iodide in water containing potassium iodide, equivalent to about 20 percent by weight of the potassium mercuric iodide used.—(*Jour. A. M. A.*, Dec. 17, 1921, p. 1971).

MERCURY AND POTASSIUM IODIDE-P. W. R.—A brand of potassium mercuric iodide-N. N. R. Powers-Weightman-Rosengarten Company, Philadelphia.—(*Jour. A. M. A.*, Dec. 17, 1921, p. 1971).

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE-SQUIBB.—Each cubic centimeter of the mixture represents 3 L+ doses of diphtheria toxin and three units of diphtheria antitoxin. It is marketed in packages of three 1 cubic centimeter ampules representing one immunizing treatment; also in packages of thirty 1 cubic centimeter ampules. For a discussion of the actions and uses of diphtheria toxin-antitoxin mixture, see New and Nonofficial Remedies 1921, p. 282. E. R. Squibb & Sons, New York.—(*Jour. A. M. A.*, Dec. 17, 1921, p. 1971).

OIL OF CYPRESS-SCHIMMEL & CO.—A brand of cypress oil-N. N. R.—For a discussion of the action and uses of cypress oil, see New and Nonofficial Remedies, 1921, p. 95. Fritzsche Bros., New York.—(*Jour. A. M. A.*, Dec. 17, 1921, p. 1971).

XEROFORM-S. AND G.—A brand of bismuth tribromphenate-N. N. R.—For a discussion of the actions and uses of bismuth tribromphenate see New and Nonofficial Remedies, 1921, p. 71. Schering & Glatz, New York.—(*Jour. A. M. A.*, Dec. 17, 1921, p. 1971).

THEOBROMINE AND SODIUM ACETATE-P. W. R.—A brand of theobromine sodium acetate-N. N. R. For a discussion of the actions, uses and dosage of theobromine-sodium acetate, see New and Nonofficial Remedies, 1921, p. 363. Powers-Weightman-Rosengarten Company, Philadelphia.—(*Jour. A. M. A.*, Dec. 24, 1921, p. 2061).

EASTMAN BARIUM SULPHATE FOR ROENTGENOLOGY.—A brand of barium sulphate for Roentgen-Ray work-N. N. R. (see New and Nonofficial Remedies, 1921, p. 58). Eastman Kodak Company, Rochester, New York.

KALMERID GERMICIDAL TABLETS POTASSIUM MERCURIC IODID.—Each tablet contains mercuric iodid 0.29 gm., potassium iodid 0.58 gm., ammonium chlorid 0.12 gm., eosin "Y" 0.0005 gm., and yields, when dissolved in water, potassium mercuric iodid 0.5 gm., with an excess of potassium iodid. For a discussion of the actions and uses of potassium mercuric iodid, see New and Nonofficial Remedies 1921, p. 198. Davis & Geck, Inc., Brooklyn, N. Y.—(*Jour. A. M. A.*, Nov. 12, 1921, p. 1573).

IODIPIN 10 PER CENT.—An iodin addition product of sesame oil containing from 9.8 to 11.2 percent of iodin in organic combination. It acts in the system similarly to the inorganic iodids. It is not broken up in the stomach, but a portion of the iodin is split off when it enters the intestine; the remaining compound is readily absorbed, and, as in the case of other fats, is largely deposited in the tissues, where it is slowly split up. Because of this behaviour, the action of iodipin 10 percent is exerted more slowly than that of the inorganic iodids. The dose is from 4 to 16 cc. (1 to 4 fluid drams) three or four times a day. Iodipin is not marketed as such, but in the form of iodipin tablets 8 grains. Merck & Co., New York.—(*Jour. A. M. A.*, Nov. 19, 1921, p. 1655)

PROPAGANDA FOR REFORM

QUINIDIN IN HEART DISEASE.—Quinidin has suddenly leaped into prominence because of its striking effects in certain forms of cardiac irregularity. To see a heart that has been constantly irregular for one or two years because of a fibrillating auricle lose its lawless and rapid beat within a few hours under the influence of this drug and resume normal rhythm and rate and maintain these for months, must attract the attention of all. The conclusions of the few clinicians who have thus far reported their investigations are in remarkable agreement as to the fact that in about half of the cases of auricular fibrillation, Quinidin is capable of restoring to the sino-auricular node the control of the heart, so that, for a time at least, the working of the heart is normal. However, while those who report on the effects of Quinidin are fascinated by the possibilities of the application of this drug in medicine, they are wisely conservative in their statements and frankly admit that much is yet to be learned concerning its proper use. It is to be hoped that the few favorable reports will not lead to the indiscriminate use of the drug in every type of irregular and rapid type of heart.—(*Jour. A. M. A.*, Dec. 3, 1921, p. 1822).

OXYGEN THERAPY.—The difficulties of oxygen therapy do not lie in any danger from undue intake of oxygen, for no abnormal increase in vital processes occurs even when mixtures very rich in oxygen are inhaled. The problem is rather one of technic in securing an actual introduction of more oxygen into the lungs under mechanical conditions of tolerable comfort. The usual haphazard methods of oxygen administration are of slight avail. When oxygen was administered with effective breathing devices in cases of cardiac insufficiency, relief of cyanosis and slowing of the pulse were secured. In pneumonia, the results were sufficiently impressive to permit the conclusion that oxygen therapy assumes a rational role in the treatment of the disease.—(*Jour. A. M. A.*, Dec. 3, 1921, p. 1820).

DELANO'S RHEUMATIC CONQUEROR.—The state chemists of North Dakota analyzed this "rheumatic cure" some years ago and reported: "This preparation is essentially starch, with a small amount of talc, containing a little quinin coated with calcium carbonate."—(*Jour. A. M. A.*, Dec. 3, 1921, p. 1838).

BUTYN.—The Council on Pharmacy and Chemistry reports that Butyn is the name applied by The Abbott Laboratories to a new local anesthetic proposed for use in place of cocain in surface anesthesia in the eye and for anesthesia of other mucous membranes. Butyn is a chemical body, of definite, nonsecret composition, namely para-aminobenzoyl-gammadinormalbutylamino-propanol sulphate. Pharmacologic investigations indicate that Butyn may take the place of cocain for surface anesthesia of mucous membranes, and that it may be superior for this purpose, and especially for use in the eye, to other synthetic anesthetics, for the reason that it can be used in materially lower concentrations. So far, however, the therapeutic value of Butyn has not been proved by adequate clinical trials. For this reason, the Council postponed the acceptance of the drug for New and Nonofficial Remedies and published a preliminary report on Butyn for the information of those who wish to put Butyn to clinical trial.—(*Jour. A. M. A.*, Dec. 10, 1921, p. 1891).

INTRAVENOUS SPECIALTIES OF THE INTRAVENOUS PRODUCTS COMPANY OF AMERICA.—This firm's list of specialties bears a striking resemblance to those of other "intravenous specialty" firms. Its Endoarsen, like Venarsen of the Intravenous Products Company of Denver, is stated to contain a cacodylate ("dimethylarsenate") together with mercury and iodid. Venarsen was reported on unfavorably by the Council on Pharmacy Chemistry, in 1915. The inferior efficacy of sodium cacodylate and its worthlessness as a spirocheticide have been demonstrated. Like other "intravenous" firms, this company advertises the intravenous administration of drugs such as sodium iodid and hexamethylenamin. The objections to and the dangers of indiscriminate administration of drugs intravenously was recently emphasized in a report of the Council on Pharmacy and Chemistry on "Some of Loeser's Intravenous Solutions".—(*Jour. A. M. A.*, Dec. 10, 1921, p. 1912).

"THE ALSAKER WAY".—R. L. Alsaker advertises a series of "Books That Teach The Alsaker Way to Health and Efficiency". Rasmus Larrsen Alsaker was graduated by Bennett Medical College, Chicago, in 1910. Alsaker's book "Curing Diseases of Heart and Arteries" seems to be the book that is pushed at present. The first part of this book contains certain elementary facts of physiology and hygiene that could be found in the ordinary common school textbooks on such subjects. The therapeutic phases of the subject are so treated that the average reader might well reach the conclusion that all physicians, except Alsaker, are either fools or rogues, and that from Alsaker alone flows the only pure, unadulterated, 100 percent medical knowledge. Alsaker's book may be counted on to have a very definite effect on the person who accepts its teachings. It may lead any patient, who because of an impaired circulatory system is under the care of a physician, to abandon such rational means as the physician might recommend and attempt self-treatment.—(*Jour. A. M. A.*, Dec. 10, 1921, p. 1909).

COD LIVER OIL IN RICKETS.—While there is a growing belief that cod liver oil is of distinct therapeutic value in rickets, many of the experiments along this line are not sufficiently objective to be entirely convincing. Now, however, Park and Howland have furnished the direct ocular proof of the effects of cod liver oil on rickets which roentgenograms afford. The results in many cases have been so consistent that they feel justified in stating definitely that cod liver oil brings about a change in the bone which, if the diet is not too faulty, amounts to complete cure.—(*Jour. A. M. A.*, Dec. 31, 1921, p. 2122).

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act, chiefly because the curative claims advanced for them were held false: Salt-Sulphur Water (Salt-Sulphur Water Company), a water found to consist wholly or in part of a filthy and decomposed putrid animal or vegetable substance and claimed to be invaluable in the treatment of inflammatory and catarrhal conditions of the stomach, intestines and diseases of the liver. Pildoras Uriseptic (Davis & Lawrence Company and New York Medicine Company), pills consisting essentially of cubebs, methylene blue, salol and kava kava, and asserted to be antigonorrheal, diuretic, antiseptic and resolvent. Boquette's Family Remedy (Boquette Remedy Company), falsely claimed to be of value for chills and fever, rheumatism, lumbago, etc., consisting essentially of a solution of Epsom salt and saltpeter, and asserted to be of value in a large number of diseases. Volta Powder (Volta Company), essentially a mixture of free sulphur, impure iron (ferric) oxid, and a trace of essential oil, and sold

as a treatment for rheumatism, sciatica, gout, etc. Carey's Marsh Root (Carey Medical Corporation), consisting essentially of plant extractives, sodium potassium salts, salicylates, aromatic oils, glycerin, water and alcohol; asserted to be of value in Bright's disease, diabetes and all urinary troubles. Sterling Injection (Western Wholesale Drug Company), a watery solution containing opium, borax, and a trace of sulphate, and recommended for the treatment of gonorrhea.—(*Jour. A. M. A.*, Nov. 5, 1921, p. 1513).

ENDOCRINOLOGY AND PSEUDO-ENDOCRINOLOGY.—R. G. Hoskins, professor of physiology, Ohio State University College of Medicine, pleads for a greater degree of discrimination on the part of physicians in evaluating not only proper data but also the various agencies either seeking support in, or exploiting, this field. The latter aspect of the situation deserves special emphasis. Those who purpose acting as purveyors to the medical profession must accept the status of purveyors. The physicians or laboratory investigator of the medical sciences shall not exploit for commercial gain the result of his studies. At the present time a commercial campaign is being carried on by a "laboratory" purporting to specialize in endocrine products. The mail of physicians is flooded with a series of postcards, each card recommending and suggesting the use of the proprietary product of this self-styled laboratory for conditions ranging from eczema to epilepsy, and from obesity to tuberculosis. This free postcard advice is reenforced by reference to "monographs" and a trade journal in which scientific medicine is systematically belittled as unpractical. This advertising campaign is ostensibly under the supervision of the enterprising Mr. Hyde, the merchant of the firm. Mr. Hyde is a profound admirer of the eminent Dr. Jekyll, the medical director.—(*Jour. A. M. A.*, Nov. 5, 1921, p. 1499).

SCHICK TEST.—The entire absence of positive reactions to the Schick test in about one dozen children should lead to the suspicion that the particular lot of toxin used is inactive. It is not unlikely that toxin in small outfits may deteriorate after leaving the manufacturer.—(*Jour. A. M. A.*, Nov. 12, 1921, p. 1594).

ESTIVIN.—This is sold by Schieffelin & Co., New York. A request for a statement of the composition of this product sent to Schieffelin & Co., by the Council on Pharmacy and Chemistry, brought the indefinite and therefore meaningless statement that Estivin is an extract of Rosa Gallica containing no alcohol or foreign ingredients.—(*Jour. A. M. A.*, Nov. 12, p. 1595).

INTRAVENOUS COMPOUND (LOFFLER).—This is exploited by the Intravenous Chemical Company of Chicago. While physicians are asked to use this preparation and told of the profits to be derived from its use, they are not informed of its composition. From the analysis of this preparation in the A. M. A. Chemical Laboratory it was concluded to be a mixture of alkali chlorate and nitrate and boric acid probably produced by fusing together the constituents. Its composition is very similar to that of Oxychlorin and Zyme-old, which were analyzed by the laboratory nearly fourteen years ago. Intravenous Compound (Loffler) is a nostrum of secret composition which physicians are asked to inject into the veins of their patients. It must be purchased in connection with some supplementary material, "a complete set of apparatus" sold by the same concern. Its successful administration is said to depend on following a technic detailed either in a booklet sent out by C. L. Loffler or given by him in a "postgraduate course" which costs physicians fifty dollars unless they have purchased six dollars' worth of another nostrum, "Thymozene". The intravenous administration of drugs is impressive. To the patient the technic and its psychic effects is striking. The dangers of intravenous medication are matters of record, and yet physicians are asked to administer this preparation, the composition of which and the effects produced by it are unknown to him.—(*Jour. A. M. A.*, Nov. 12, 1921, p. 1591).

IODIN AND GOITER.—According to Marine, if the iodin store in the thyroid is maintained above 0.1 percent, no hyperplastic changes and, therefore, no goiter can develop. The studies of Marine and Kimball show that simple or endemic goiter can be prevented by the administration of from 3 to 5 mg. of iodin twice weekly, over a period of a month and repeated twice yearly. Is it not time for the medical profession to give special attention to this? If prevention of goiter is good preventive medicine, it is better preventive surgery.—(*Jour. A. M. A.*, Nov. 12, 1921, p. 1574).

MIDOL HEADACHE TABLETS.—Midol was analyzed in the A. M. A. Chemical Laboratory in 1912. At that time the chemists reported that Midol was sold in the form of tablets and to contain amidopyrin (first introduced as pyramidon) as their essential constituent. Amidopyrin is a pyrazolon derivative related to antipyrin, and it has no place in preparations for self drugging.—(*Jour. A. M. A.*, Nov. 19, 1921, p. 1674).

SELENI-BASCCA.—A campaign of free publicity is carried on for an alleged remedy for cancer. The press agent material has been of two kinds—for medical journals and for newspapers. That for medical journals has been sent out on the stationery of the Medical News Bureau, 77 Seventh Ave., Brooklyn, N. Y., D. E. Woolley, Manager. The items sent out to medical journals stated that the "Basic Cancer Research" had been organized to develop a treatment of cancer by the use of selenium and tellurium. The material received by newspapers was sent out by the "Cosmopolitan Cancer Research Society", 847 Union St., Brooklyn (the same address as the Basic Cancer Research). The secretary of the Cosmopolitan Cancer Research is D. E. Woolley. The name of the preparation which the Basic Chemical Corporation puts out is Seleni-Bascca. A specimen, labeled "SELENIBASCCA. A mixture of Colloidal Selenium in tablet form", was examined in the A. M. A. Chemical Laboratory. The tablets were found to contain only about 1.3 percent of selenium, and the product was not colloidal as claimed. The composition of Seleni-Bascca resembles that claimed for Sulpho-Selene, a preparation reported on by the Council on Pharmacy and Chemistry some years ago, but it contained no bile salts (a constituent claimed to be present in Sulpho-Selene).—(*Jour. A. M. A.*, Nov. 19, 1921, p. 1672).

SERUM FOR PERNICIOUS ANEMIA.—"Ph. Rahtjen, A. M., Ph. D.," Pasadena, Calif., informs laymen that he has immunized goats against the germ of pernicious anemia and that patients have responded favorably to the "serum". Reference to medical literature does not disclose just what Rahtjen's serum is, and a search of American medical literature for some years past fails to disclose any publication by Rahtjen on any subject. In 1917 the Rahtjen Tuberculosis Sanatorium, San Francisco, Calif., exploited the Rahtjen Cure for Tuberculosis with the claim that "the remedy seems to cure tuberculosis in all its forms with equal celerity and certainty"; and yet people are still dying of tuberculosis. In 1920, so the newspapers had it, Rahtjen was offering a "New-Life Fluid" which was a long step forward to counteract old age. This was in March, 1920, yet people continue to grow old. Acording to recent newspaper accounts, Rahtjen is making his extract from Mexican bulls and cows; the first for males and the second for females.—(*Jour. A. M. A.*, Nov. 26, 1921, p. 1753).

BOOK REVIEWS

NOSTRUMS AND QUACKERY. Articles on the nostrum evil, quackery and allied matters affecting the public health reprinted with or without modifications, from *The Journal of the American Medical Association*. Volume II, illustrated, 832 pages. Published by the American Medical Association, 535 N. Dearborn St., Chicago, Ill. Price, $2.00.

Ten years ago the American Medical Association published the first edition of the first volume of this book. A year later a second, and enlarged, edition of the first volume was issued. Since that time *The Journal of the American Medical Association* has published, week by week, articles on the nostrum evil, quackery and allied matters affecting the public health. All this material has been collected and appears in the present volume.

Quackery can never be defended; the "patent medicine" business, however, need not be fundamentally fraudulent. There is a place for home remedies for the self-treatment of simple ailments. Unfortunately, the home remedies of today are, generally speaking, those secret nostrums commonly called "patent medicines" and the methods of "patent medicine" promotion make these products a menace to the public health. The average "patent medicine" is so advertised as to frighten well people into the belief that they are sick for no other purpose than that of causing them to purchase the nostrums.

The present volume is a veritable encyclopedia of information on the subject it treats. The book contains nineteen chapters. The titles of some of these are: "Alcohol, Tobacco and Drug Habit Cures," "Consumption Cures," "Cosmetic Nostrums," "Deafness Cures," "Epilepsy Cures," "Female Weakness Cures," "Nostrums for Kidney Disease and Diabetes," "Medical Institutes," "Miscellaneous Nostrums," "Obesity Cures," "Quackery of the Drugless Type" and "Tonics, Bitters, Etc."

This partial list of chapters gives but a poor idea of the vast fund of information contained in the book. To make the volume still more valuable it contains an index of twenty-two pages, two columns to the page, which includes references to every article appearing in the first volume of "Nostrums and Quackery" as well as to all articles in the present volume.

The book is free from stilted or highly technical language. The articles have evidently been written with the idea that the facts they contain belong to the public. In the Preface, it is emphasized that the work which this volume represents is wholly educational in character—not punitive. "The matter that appears in this book has been prepared and written in no spirit of malice and with no object except that of laying before the public certain facts the knowledge of which is essential to a proper conception of community health."

HISTORY OF MEDICINE, WITH MEDICAL CHRONOLOGY, SUGGESTIONS FOR STUDY AND BIBLIOGRAPHIC DATA, by Fielding H. Garrison, M.D., Lt.-Colonel, Medical Corps, U. S. Army, Surgeon General's Office, Washington, D. C. Third edition, revised and enlarged. Octavo of 942 pages, with 257 portraits. W. B. Saunders Company, Philadelphia and London, 1921. Cloth, $9.00 net.

Every medical student or busy practitioner should be interested in the history of medicine. Much of what has been written by Dr. Garrison reads like a novel and holds the attention of the reader if he is interested in following the development of medicine and surgery from ancient times down to the present. As has been stated in the introductory chapter, the history of medicine is the history of human fallibility and error. The history of the advancement of medical science, however, is the history of the discovery of a number of important fundamental principles leading to new views of disease, to the invention of new instruments, procedures, and devices, and to the formulation of public hygienic laws, all converging to the great ideal of preventive or social medicine; and this was accomplished by the arduous labor of a few devoted workers in science. The development of science has never been continuous nor even progressive. Ideas of the greatest scientific moment have been throttled at birth or veered into a blind alley through some current theologic prepossessions, or deprived of their chance of fruition through human indifference, narrow-mindedness, or other accidental circumstances. It is no exaggeration to say that science owes most to the shining individualism of a few chosen spirits. Apart from this, "the success of a discovery depends upon the time of its appearance."

"The conquest of communicable diseases, the attainment of painless, shockless, deathless surgery, the manifold devices of sanitation, the recognition of an interrelation between health and disease and social-economic conditions, the wide-spread concern about industrial poisoning, trade diseases and accidents, the movement for wholesale destruction of noxious insects, parasites, reptiles, and vermin, the relation of the neuroses to crime and the sexual genesis of crime, the relation of the internal secretions to the neuroses and insanities, nay, even to cerebration itself, have been a few of the trends of recent medicine. The influence of disease itself upon the trend of human history in the past is still an unwritten chapter, thrown into striking accidental relief by the triumph of sanitation over infectious diseases in the European War."

In the preparation of this book the author has taken advantage of the Surgeon General's library, one of the most comprehensive in the world, though every effort has been put forth to obtain information from any source that would add to the material at hand. The whole book, aside from the appendices and index, has been divided into twelve chapters, and the enumeration of their titles gives a fair idea of the scope of the work: I. The Identity of All Forms of Ancient and Primitive Medicine. II. Egyptian Medicine. III. Sumerian and Oriental Medicine. IV. Greek Medicine. V. The Byzantine Period (476-732 A. D.). VI. The Mohammedan and Jewish Periods. VII. The Medieval Period (1096-1438), Cultural and Social Aspects of Medieval Medicine. VIII. The Period of the Renaissance, the Revival of Learning, and the Reformation (1453-1600). IX. The Seventeenth Century: The Age of Individual Scientific Endeavor. X. The Eighteenth Century: The Age of Theories and Systems. XI. The Nineteenth Century: The Beginnings of Organized Advancement of Science. XII. The Twentieth Century: The Beginnings of Organized Preventive Medicine.

EYE, EAR, NOSE AND THROAT. Volume III, 1921, of the Practical Medicine Series, under the editorship of Dr. Casey A. Wood on the Eye, Dr. Albert H. Andrews on the Ear, and Dr. George E. Shambaugh on the Nose and Throat. The Year Book Publishers, Chicago. Price of a volume, $1.75. Price of the series of eight volumes, $12.00.

As usual this is a very interesting volume and will be read with interest and profit by specialists. Some of the abstracts are a reflection of articles on military experiences together with references to histories

A Bloodless Field

is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 **Suprarenalin Solution** slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work **Pituitary Liquid** (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's Sterile Catgut Ligatures are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

BALTIMORE

(Continued from page 38)

of cases arising from battle injuries or camp diseases. There are also references to lethargic encephalitis and focal infections as applied to the special branches of medicine under consideration. As in previous volumes, over half of the book is devoted to the eye, and but little of a real progressive nature, as reported in current literature, has been omitted. The part devoted to diseases of the ear offers abstracts of many articles concerning the diagnosis and treatment of diseases of the sound perception apparatus, and also the late advances in mastoid surgery as based upon extended experience through the influenza epidemic. In the part covering the nose and throat much is devoted to accessory sinus disease in addition to the usual subjects. While it has not been possible to abstract anything and everything that would appear in print concerning the diseases under discussion, yet the editors have succeeded well in furnishing abstracts of papers on practical rather than experimental subjects, and they have taken the cream of the articles that have appeared in current literature.

TUBERCULOSIS AND HOW TO COMBAT IT, by Francis M. Pottenger, M.D., A.M., LL.D., F.A.C.P. C. V. Mosby Co., St. Louis. Cloth, $2.00 net.

This is a book for the patient. It describes the nature of the disease with which the patient is suffering, pertinent facts concerning the source and manner of infection, the development of resistance or immunity, the course and care of the disease when once established, the things that interfere with cure, and the maintenance of health when once attained. In the main the book answers the questions that are most often asked by tuberculous patients, and it tells in an understandable way what must be done in order to combat the disease, and this includes many subjects, such as open air, rest, exercises, food, baths, climate, tuberculin treatment, sanitarium treatment, home treatment, etc.

PRACTICAL PSYCHOLOGY AND PSYCHIATRY, by C. B. Burr, M.D., Medical Director of Oak Grove Hospital, Flint, Michigan. Fifth edition, revised. F. A. Davis Company, Philadelphia. Cloth, $2.00 net.

This is a ready reference book for the nurse and practitioner, and discusses briefly psychology in the various forms of insanity, with causes, course and approved method of management. The author long has been known as an expert in mental and nervous diseases, and is competent to handle this subject in an authoritative manner.

THE ETIOLOGY OF EPIDEMIC ENCEPHALITIS

Certain resemblances of epidemic (lethargic) encephalitis to poliomyelitis have stimulated two similar investigations, which resulted in opposite conclusions. Amoss found that the serum of patients convalescing from encephalitis does not protect monkeys against the inoculation of poliomyelitis virus, whereas Neustaedter, Larkin and Banzhaf found that it does result in protection. We may assume, *a priori*, that the difference in results is due to the method; Neustaedter and his co-workers incubated the virus with the serum, while Amoss followed the technic he used previously with Flexner and Eberson. He administered the serum intraspinally and then injected large quantities of virus intravenously. The negative results of Amoss seem convincing, but the slight protection proved by the experiments of Neustaedter demands explanation. Several years ago it was found that the serum of patients suffering from herpes zoster was able to neutralize the poliomyelitis virus. It is therefore possible that the encephalitis virus is, like that of zoster, kindred, but not identical with the virus of poliomyelitis.—*Jour. A. M. A.*, Dec. 10, 1921.

OPTIC NEURITIS IN SERUM SICKNESS

In the case reported by V. R. Mason, Los Angeles (*Journal A. M. A.*, Jan. 14, 1922), certain abnormalities were discovered which pointed to involvement of the central nervous system in the reaction of the organism to a foreign serum. The patient was admitted to the hospital on the second day after the onset of acute lobar pneumonia. Type I pneumococci were grown from washed sputum. During the third, fourth, fifth and sixth days of the disease, the patient received 500 c.c. of Type I antipneumococcus serum intravenously. His temperature fell by crisis on the seventh day of the disease. Severe serum sickness appeared on the ninth day, and was present for fourteen days. During the course of the serum disease, a well marked, bilateral optic neuritis was observed. This was associated with marked lethargy and an increase of the globulin and cellular content of the cerebrospinal fluid. The optic neuritis was not associated with demonstrable visual disturbances. At the end of three months, the fundi had returned to normal in appearance.

METHODS OF PRECISION IN DIAGNOSIS OF DIABETES

In the cases cited by Henry J. John, Cleveland (*Journal A. M. A.*, Jan. 14, 1922), the condition was diagnosed as diabetes mellitus by the patient's physician on the basis that she had sugar in the urine. She was put on a rigidly restricted diet and kept on it until she had lost almost 50 percent of her weight; but she still showed sugar in the urine. Further examination revealed that she had a normal blood sugar content; and her ability to utilize carbohydrates —the glucose tolerance test—was demonstrated to be normal by a perfectly normal curve; that is, she was able to utilize all the carbohydrates one could give her. This was strikingly demonstrated later on, when a heavy carbohydrate diet, high in calories as well, failed at any time to bring her blood sugar above the normal level. These findings show clearly that the case was not one of diabetes, in spite of the fact that there was sugar in the urine, but a case of a kidney permeable to sugar, a fairly common condition.

CALCREOSE

CALCREOSE (calcium creosote) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has all the pharmacologic activity of creosote but has no untoward effects on the stomach; therefore it may be taken in comparatively large doses for long periods of time.

In the treatment of acute inflammations of the respiratory tract and infections of the gastro-intestinal tract CALCREOSE has been used with good success.

CALCREOSE can be given in comparatively large doses for long periods of time without any objection on the part of the patient.

PRESENT DAY CLINICAL CARDIOLOGY*

By

GEORGE R. HERRMANN, M. D.

ANN ARBOR, MICHIGAN

(From the Department of Internal Medicine of the University of Michigan)

Two decades ago physicians were content to classify the disturbances of the pulse as regular or irregular. Great advances, however, have been made within the last decade and a half in the study of heart disease, and especially of the disorders of rate and rhythm. Sir James Mackenzie of Scotland, with his simple polygraph but a keen unequaled power of observation, gave the first impulse and inaugurated a new era in the study of heart disease, by his explanation of the mechanism of the persistently irregular pulse. Wilhelm Einthoven of Leyden, a Dutch physiologist, applied the string galvanometer to the study of the electrical phenomena of cardiac mechanism. This instrument, the electrocardiograph, in the hands of the inventor and Sir Thomas Lewis of London, has revolutionized our knowledge of the mechanism of the heart action. We are indebted to these pioneers of modern cardiology for the firm concrete present-day conception of heart disease. Their writings, with those of a few others in this country and abroad, have dispersed all the vague intangible ideas that more or less have mystified the practice of cardiology and instead have established a definite science founded on physiological, anatomical and etiological facts. What the present decade will produce no one can predict. Our research efforts are directed toward the corroboration or verification of some of the physiological points and the collection of clinical and pathological statistics.

In the diagnosis of heart disease, a careful clinical history usually points to important etiological factors as acute rheumatic fever, chorea, "growing pains," repeated attacks of tonsilitis, syphilis, or some other severe infectious disease, or exophthalmic goitre. A negative history, however, in a case with mitral stenosis does not discount the diagnosis of rheumatic heart disease. Likewise the denial of venereal disease does not influence one in the presence of a free aortic regurgitation with an aortitis or other stigmata of syphilis including a positive complement fixation test. Except for cases of cardiac neurosis and effort syndrome, a reliable history is the index of the functional condition. If there has been a cardiac break, that is, heart failure of the congestive type, there is a story of orthopnea, cyanosis, edema, pain under the right costal margin, from the stretched liver capsule as a result of engorgement, etc. The anginal type of heart failure is accompanied by graphic description of the typical radiating cardiac pain of angina pectoris. The limit of cardiac function is further defined by the history as to whether the patient is able to carry on his usual activities, or only slightly to moderately curtailed activity, or only greatly diminished activity, or no activity whatsoever without distress.

The physical examination, however, yields the *reliable signs* upon which we can safely base our conclusions that a patient has, or what is equally important, does not have heart disease. By our term heart disease, we mean actual or potential myocardial changes due to functional or organic damage to the heart muscle and congenital cardiac malformations, which will sooner or later produce symptoms.

In the general cardiovascular inspection, *distinct engorgement of the neck veins,* that is, overdistention signifying an abnormally increased venous pressure in veins raised above the level of the heart's base is evidence of heart disease. Increased abdominal and thoracic muscle tension, or intra-abdominal and intrathoracic pressure including mediastinal tumors must, of course, be ruled out before concluding that the sign is the result of cardiac embarrassment with engorgement of the right auricle.

Palpation may reveal *a definite thrill,* a distinct "purr" at the apex or over the base of the heart. A real thrill is the palpable counter-

* Given before the Fort Wayne Medical Society, December 20, 1921.

part of the rumbling apical diastolic murmur of mitral stenosis; a loud rasping basal systolic murmur of aortic stenosis, or congenital pulmonary stenosis, patent ductus arteriosis or interventricular septum defect; or more rarely the basal diastolic murmur of aortic insufficiency. This finding, a thrill, when unmistakable, is a dependable sign of heart disease. The vibration of the chest wall from an overactive heart is to be differentiated.

Cardiac enlargement is positive evidence of heart disease. Definite clinical or bedside signs are few and not infallable. The outermost part of the circumscribed apex impulse is the best guide to the size of the heart. In normal and moderately large hearts it corresponds to the left border, while in very large hearts it indicates enlargement but not the extent of the left border to the left. An apex impulse extending outside the midclavicular line or more than 11.5 c.m. to the left of the midsternal line in the 5th intercostal space, or better, in the 6th intercostal space, in the absence of causes for displacement gives a clinical indication of heart disease. Orthodiagrams or teleroentgenograms give exact measurements and consequently exact evidence of enlargement, when the latter is present, thus diagnosticating heart disease.

The rumbling *apical diastolic murmur,* the characteristic diagnostic finding in developed mitral stenosis denotes rheumatic heart disease, in which the myocardium is always directly affected. The presence of Aschoff bodies in the myocardium is proof of the involvement of the heart muscle in acute rheumatic fever.

The high pitched *basal diastolic murmur,* characteristic of frank aortic insufficiency designates usually rheumatic heart disease in a young individual and a syphilitic heart disease in the middle aged individual. Myocardial involvement is, as a rule, more widespread and more severe in syphilitic aortic insufficiency than in that of rheumatic origin. The root of the aorta is affected and the coronary arteries are involved especially at their origins.

Aneurism of the aorta is a manifestation of cardiovascular syphilis, which is not infrequently, especially in the south, a presenting complication which signifies accompanying heart disease.

Generalized arteriosclerosis produces nutritional disturbances enough in the myocardium to impair the structure as well as the function of the latter.

Chronic Nephritis likewise through toxins, blood changes, arterial changes, blood pressure changes, or what not, damages the heart muscle invariably and produces great cardiac enlargement as shown in a series of 60 cases which were studied clinically, electrocardiographically, and pathologically. The series shows ventricular weights of 250 G. and over, and myocarditis in every case in which the microscopic study of the kidneys showed chronic degenerative changes.

Persistent hypertension with the blood pressure reading constantly 25 to 30 m.m. of mercury higher than the accepted average normal level for the patient's age and sex, always results in cardiac enlargement and myocarditis. Our series showed ventricular weights of 250 G. and over in all cases with persistent blood pressures of 140 m.m. Hg. and over.

The presence of any one of the grave disturbances of cardiac rhythm as *alternation, heart block, auricular flutter,* or *auricular fibrillation* is sufficient bases for the diagnosis of heart disease.

Any one of the etiological factors, the signs, or the valve lesions would suffice as a topic for a lengthy discourse. We have selected the last mentioned group of reliable signs of heart disease for fuller discussion. The disturbances of the cardiac mechanism, though of the greatest importance, have been more or less unemphasized until clinical electrocardiography analyzed them and gave the basis for the simple rules and tests, which make possible the accurate bedside differential diagnosis.

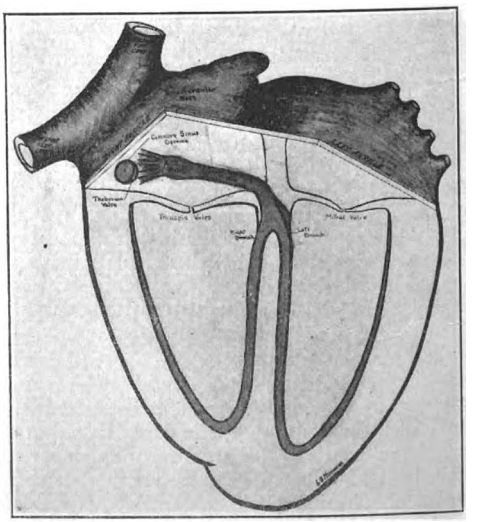

Figure 1. A diagrammatic representation of the special structures that control the origin and conduction of the impulses which regulate the cardiac mechanism.

At this point it seems logical to take up, in review, the special anatomy (Fig. 1) and physiology of the heart which does not receive very great emphasis even in our present day fundamental courses. The first structure of importance is the sino-auricular or Keith Flack Node, the so-called pace-maker of the

human heart which lies at the junction of the superior vena cava and the right auricle. The auriculoventricular or Tawara node, lies in the edge of the auricular septum tissue at the posterior and right border just anterior to the thebesian valve of the coronary sinus. The auriculo-ventricular or His bundle proper begins at this node and coursing almost horizontally forward and to the left, but keeping on the right side of the central fibrous body, to the anterior part of the membranous part of the interventricular septum, the bundle forks. The left branch perforates the membrane, enters the subendocardial space of the left ventricle immediately beneath the point of junction of the anterior and right posterior cusp of the aortic valve. It branches freely almost immediately and spreads out under the endocardium, as the freely anastomosing syncytial Purkinje network. The right division soon becomes subendocardial but passes downward in the moderator band or its representative proceeding directly to the base of anterior papillary muscle as a single strand, before breaking up into the subendocardial arborizations of the Purkinje tissue lining the right ventricle. The vagus nerves have fibers distributed to the sino-auricular and auriculo-ventricular nodes.

The physiology or mechanism of the normal heart beat is intimately associated with the special structures just described. The practical theory is that there is a constant building up (anabolism) of certain combined material having a distinct potential energy. This metabolic process occurs at a certain constant rate regularly and uniformly in every heart muscle cell. The accumulation of energy rises to a constant level where it "touches off" and falls promptly to zero. The level of discharge is always reached in the same time. This specialized neuromuscular tissue in the sino-auricular node, the pacemaker, holds control by virtue of its supreme lability or its faster rate of anabolism assuming that the process in the ordinary heart muscle is on a slower incline. The physico-chemical changes taking place in the sino-auricular node produce an electrical stimulus, a difference of potential, which can be detected by the string-galvanometer or electrocardiograph. This stimulus or impulse spreads with equal speed in all directions through the auricular muscle, "touching off" all the products of anabolism and liberating the energy of the auricular contraction. The impulse is then taken up by the auriculo-ventricular node transmitted through the His bundle and by its branches to the subendocardial arborizations of the Purkinje network of each ventricle. The time consumed by the stimulus in passing through the auriculo-ventricular node and His bundle normally never exceeds .17 to .18 seconds (the P. R. interval of the electrocardiogram) while the intraventricular spread takes place in .06 to .08 seconds (the QRS interval of the electrocardiogram). Thus the spread of the impulse or excitation wave is very rapid, the rate of transmission through the specialized tissues being 5,000 m.m. per second, while that through the ordinary heart muscle tissue is only 500 m.m. per second. The excitation of all parts is almost instantaneous, the energy is liberated and contraction results.

The disturbances of this mechanism under the influence of disease are what interests us chiefly. The pathological physiology gives us a clear conception of the clinical disorders of cardiac action.

The vagus nerves are distributed to the sinus node and have been proven to exert a strong inhibitory influence over the rate of stimulus formation. When the restraint is constant as in vagatonic individuals, athletes, or in basal brain tumor or meningitis, hypertension, pregnancy, jaundice, and in acute febrile convalescent cases, or following pilocarpin administration we find a slowing to a heart rate of 60 or even as low as 50, which we term *Simple Sinus Bradycardia.*

If the vagus tonus is periodic, as is often associated with respiration, we have a regularly repeated irregularity, the periodic waxing and waning of especially the youthful heart, also strikingly demonstrated by palpation of the dog's heart. This we term *Sinus Arhythmia.*

Release of the vagus inhibition by paralysis, as produced by atropin, increases the heart rate to between 150-160 at the most. Exercise, excitement, fright, nervousness, the effort syndrome, fevers and hyperthyroidism and sometimes unknown causes produce fairly persistent increases in the heart rate. This condition we term *Simple Sinus Tachycardia.*

Heart Block depends for its type upon where the affection strikes and to what extent the special structures are involved. *Sino-auricular block* is occasionally attributed to excessive vagus inhibition producing a completely dropped beat now and then. In this condition auricles as well as ventricles fail to contract, as the block is in the pacemaker. In the persistent S-A block, the next most irritable part of the specialized tissue, the auriculo-ventricular node or if this too is damaged, the junctional tissues assume the role of pacemaker and establish an auriculo-ventricular or junctional rhythm with or without retrograde stimulation of the auricle.

Auriculo-ventricular block results from pathological lesions in the A-V node or His bundle and may be of varying degrees. The first stage of A-V block is where there is only *delayed conduction in the His* bundle. The next lowest

grade is where one auricular impulse out of 8 to 20 fails to pass the His bundle and consequently fails to produce ventricular excitation, and a dropped beat is the result from this 20 to 19, or 8 to 7 *partial heart block*. We may get any degree of auriculo-ventricular block to such high degrees as 2 to 1, 4 to 1, even 6 to 1, mixtures or irregular blocking and finally *complete A-V block* with independent auricular and ventricular rhythms, with the regular idioventricular rhythm at a rate of 40 or less.

Besides blocks in the A-V or His bundle, we may have delayed conduction, incomplete or complete block in either the right or left branch of the His bundle, these we term *incomplete or complete bundle branch blocks*. Anatomically, the right branch proceeding as a single strand to the anterior papillary muscle on the right is more prone to injury than the left branch which breaks up just as it enters the subendocardial space of the left ventricle and consequently an extensive lesion is required to produce a block. Clinical experience agrees with these anatomical facts. In a series of 6,000 routine electrocardiograms we collected 32 cases of complete right bundle branch block and only one case of left bundle branch block. In the same series of 6,000 curves there were 32 incomplete right and four incomplete left bundle branch blocks. Occasionally the fibrosis which causes bundle branch block on one side spreads through the upper septum and involves the other side producing double bundle branch block or interventricular block with resulting complete heart block.

Arborization block due to wide spread lesions in the freely anastomosing Purkinje network cannot be considered established as a clinical entity.[12]

Extrasystoles, premature or ectopic beats, originate at some point other than the sinus node and break the regular rhythm by coming earlier than the regular beat. Some point in the auricular or ventricular muscle or in the junctional and most rarely in the lower part of the sino-auricular node becomes more irritable, due to some focal pathology or pathological physiology, than the tissues in the head of the sino-auricular node and consequently the anabolism rises even more rapidly or comes to its "touching off" level sooner and discharges an impulse, which getting into the specialized tissue spreads to all parts and the premature contraction results. After this phenomenon, there is a post-extrasystolic pause, which is required to build up the energy for the next regular beat. The premature touching off seems to have destroyed the immature potential energy more completely, hence the longer building time, the post-extrasystolic pause, necessary. According to the point of origin extrasystoles may be auricular, junctional, or ventricular. Interpolated extrasystoles are thrown in in mid-diastole and do not disturb the rhythm at all, that is, there is no long post-extrasystolic pause.

Alternation or Pulsus alternans is a condition characterized by alternate stronger and weaker regularly occurring and evenly spaced beats. It is supposed to be due to the contraction of different numbers of ventricular muscle scrolls at alternate systoles. The sign is evidence of cardiac fatigue and in the slow regularly beating heart is of grave prognostic significance, while in a paroxysmal tachycardia it is negligible.

Paroxysmal tachycardia is an attack of sudden onset and sudden offset coming on more or less frequently. The heart rate rises suddenly from the normal to rates between 100 and 220 per minute. The paroxysms are made of longer or shorter runs of extrasystoles occurring regularly. In other words, an ectopic focus dominates the rhythm. The new focus may be in the auricular muscle outside the sinus node, in the junctional tissues, or in either ventricle. The latter two types are quite rare, the junctional type in two cases seen seemed to be more of a permanent tachycardia. The ventricular type is of very grave significance as it is, so far as known, always associated with coronary occlusion as pointed out in our series of four cases[11].

Auricular flutter has been recently shown by Lewis[5] to be due to stimulation of the auricle by a single and continuous wave, circulating usually around the mouths of the superior and inferior venae cavae. A circular continuous contraction wave at a rate of 220 to 350 per minute, usually 260 to 329 instead of the normal wave proceeding from the sinus node and extending out into the auricular tissue and dying out. The auricular action is rapid and weak. The His bundle does not conduct an impulse to the ventricle, with each action of the auricle, there is characteristically a 2:1 block, the ventricle contracting only half as often as the auricle. The block may be of higher grade or may vary from time to time, producing an irregular ventricular action.

Auricular fibrillation likewise has recently been shown by Lewis[5] to be related in mechanism to auricular flutter, but different in that instead of the single circus wave, there are circulating sinous waves propagated and revolving perpetually, following varying paths colliding and apparently following the re-entrant paths of least resistance. As a result, the auricle does not contract, however, 450 to 600 impulses are generated per minute and the auricular action consists of fibrillary twitchings with consequent dilatation from engorgement. The His bundle is showered with a great number of irregularly placed haphazard impulses, of

varying intensity, the greater of these are conducted to the ventricle. The ventricular action following this type of stimulation is likewise absolutely irregular. Some stimuli come so close to preceding stimuli and are so weak that although they produce ventricular contractions the latter are so weak that the aortic pressure is not overcome, the semilunar valves are not opened and no pulse wave is sent forth. This accounts for a higher heart rate than the pulse rate, the difference is what we term the pulse deficit.

Now having briefly described all the disturbances of the cardiac mechanism, the important ones of which we mentioned as the diagnostic signs of heart disease, we may proceed to the clinical differentiation of these disorders.

We can divide the abnormal rhythms into those that are always and usually regular and those that are always and usually irregular. Sinus bradycardia, sinus tachycardia, bundle branch block and complete heart block are regular. Paroxysmal tachycardia, auricular flutter, and partial heart block are, as a rule, regular but very short paroxysms of tachycardia and irregular or varying blockings in auricular flutter and partial heart block may in occasional instances produce an irregular pulse.

Alternation or pulsus alternans is a regular irregularity presenting no real disturbance in rhythm but merely a difference in force of every other regular beat. Sinus arhythmia is a periodic irregularity, the waxing and waning rhythm so often associated with deep breathing in the normal youthful heart. Extrasystoles usually disturb the rhythm considerably, occasionally the regular spacing of extrasystoles in bigeminy, trigeminy, etc., gives a sense of regularity to the disturbance. Frequent irregularly placed extrasystoles, especially those of auricular origin, may produce a disturbance simulating very closely auricular fibrillation. Auricular fibrillation is an absolute irregularity in force of beats as well as in rhythm.

DIFFERENTIAL DIAGNOSIS

General observations together with a few simple tests are sufficient for practical clinical differential diagnosis of the disturbances of cardiac mechanism. Following the observation of the rhythm and routine counting of the heart rate and pulse rate, the careful observation of the rate for constancy is employed in every case with a tachycardia. In this test, the apex rate is counted for a full minute at five and ten minute intervals and in different positions with and without vagus stimulation. The paroxysmal auricular tachycardia or any other tachycardia with an abnormal point of origin shows remarkable constancy of rate with variations of not more than two, from minute to minute under various conditions. The tachycardias of sinus origin show distinct, though often only slight, variations in rate from minute to minute and under varying conditions.

The vagus stimulation tests further differentiate the cardiac disturbances with rapid rates. Pressure on the eyeballs or on the vagus in the carotid sheath in the neck or the Valsalva or Mueller breathing experiments can be used.

Auricular flutter reacts most constantly and characteristically to this test. In this disturbance, the His bundle is very susceptible to vagus influences, which increase its resistance, that is, decrease its conductivity, thus producing auriculo-ventricular block. The two to one block, which is always present, is increased by vagus stimulation and the ventricles may be held in check for thirty or more auricular beats, but the effect is only temporary, lasting for only short periods of 5 or 6 short runs of auricular activity with rare ventricular responses.

Paroxysmal auricular tachycardia may be completely stopped in about fifty per cent of cases, that is, the pulse will drop suddenly from its high level around 240 to the normal rate of about 80 and remain so. If this total effect is not obtained, there is no effect whatsoever, which is characteristic in the other fifty per cent of cases.

Simple sinus tachycardia shows usually only a slight slowing effect. This slowing of the heart slightly or moderately produces the characteristic discrepancy in the minute rates.

The last and most important simple test is that of *increasing the heart rate*, by exercise, amyl nitrite or atropin. The benign and moderately grave irregularities, as sinus arhythmia, extrasystoles, and partial heart block, when of low grade and of irregular or mixed type, and even auricular flutter when irregular due to comparatively rare irregular blocking, all become regular when the heart rate reaches 120 to 140 at the most. An irregularity, which persists or becomes more irregular at 130 to 140, is auricular fibrillation.

Alternation, the regular alternate variation in the strength of the heart beat is accentuated, when greater work is demanded of the heart in the increased rate. The sphygmanometer test with the pressure just below the systolic level will allow to pass only the alternate beats that produce the high systolic pressure, consequently the pulse rate at the wrist is just half of what it is after the pressure is dropped 20 to 30 m.m. of mercury or dropped to zero.

Bigeminy, due to alternate extrasystoles, may show differences in the blood pressure levels, but the normal beats and extrasystoles are not evenly spaced. There is a coupling effect due to the post extrasystolic pause. The bigeminy disappears with exercise, while the alternation is accentuated.

Extrasystoles and partial heart block both disappear at the higher rates. Gradual disappearance of the irregularity with the gradually increasing rate suggests extrasystoles while a sudden doubling or an increase of the rate by a regular factor suggests heart block. The main point, however, in the diagnosis is the presence of a premature heart sound followed by a post extrasystolic pause in the case of extrasystoles, as the rate drops back to normal. In heart block, under the same circumstances, no sound is heard at the apex and the pause is longer, amounting to almost two cardiac cycle lengths.

If the heart rate is 40 or less, heart block is present and if it remains so, unaffected by exercise, amyl nitrite, or atropin, complete permanent auriculo-ventricular block with an idioventricular rhythm is present. If of a high grade partial or temporary complete heart block type, the exercise or drugs may cause a sudden rise to twice, thrice, or four times the rate. Sinus bradycardia is only gradually overcome and the rise in rate is not very great. Furthermore, the rate practically never drops below 50 per minute and is always regular. The presence of any etiological factor, as jaundice, meningitis, brain tumor, or other evidences of vagatonia help to make the diagnosis of sinus bradycardia as much as fever hyperthyroidism, etc., help in differentiating sinus tachycardia.

DISCUSSION

Thus the observations of rate, the vagus tests, and the exercise or drug tests suffice to make bedside diagnoses of the nature of the cardiac disorders. Such being the case, the question of the necessity of instruments of precision, such as the string galvanometer or electrocardiograph of Einthoven will arise. Certain accomplishments and advantages, however, must be recognized. The string galvanometer has made possible the complete analysis of the cardiac mechanism and given us a clear conception of the physiology and pathological physiology of the heart beat. Electrocardiographic tracings make the differential diagnosis absolutely final in all cases.

In certain cases, electrocardiograms are the only means of making a reliable diagnosis. These cases are few, but of importance. In the group of heart blocks the diagnosis sino-auricular block can be established only by electrocardiograms which show the absence of auricular activity as well as the failure of ventricular activity. In the lowest grade of auriculo-ventricular block, that in which there is merely a delayed conduction, we have as the only clinical suggestive evidence a split first sound, a presystolic gallop rhythm, due to the fact that the sound of auricular systole is so far separated from that of ventricular systole, that the two are not blended as is usually the case. The split first sound is by no means pathognomonic. Electrocardiograms show this distinctly as a P-R interval greater than .17 to .18 seconds. The exact grade of heart block is also best established by electrocardiographic curves.

Bundle branch blocks can be diagnosed only by electrocardiograms, which show characteristic broadening of the QRS interval or delay in the intraventricular conduction and diphasic T waves. There may be a suggestion of this disturbance in the presence of split heart sounds, especially a splitting of the second sound, a protodiastolic gallop rhythm, due to slight asynchronism of the ventricles and consequently asynchronous closure of the semilunar aortic and pulmonary valves. The reduplicated second sound, however, may be present in the absence of bundle branch block.

The point of origin of paroxysmal tachycardia can be definitely established only by electrocardiograms, though suggested by the clinical facts mentioned. When of short or only moderate duration infrequent or frequent and only slightly incapacitating it is usually of auricular origin; when persistent, it is of junctional origin; and when associated with severe persistent angina, shock, and pulmonary edema, it is probably of ventricular origin due to coronary thrombosis.

TREATMENT

The pharmacologic action of drugs on the cardiac mechanism is being analyzed by electrocardiographic means. Lewis[6] has explained the action of Quinidin, the newest and most spectacular of the drugs used in cardiology. He has shown that Quinidin increases the refractory period of the auricular muscle and thus makes auricular fibrillation impossible. The action of the Quinidin in clinical cases of auricular fibrillation can be best controlled and carefully watched as it passes through impure flutter to normal mechanism. Likewise digitalization may be controlled by observing the changes in the T waves, and by the accurate recording of the ventricular rate.

The treatment in heart disease is a lengthy chapter and cannot be lightly passed over. At the same time, we can merely touch upon a few points in a general discussion of this type.

The differentiation of the disturbances of cardiac mechanism is absolutely essential in the scientific treatment of heart disease. Digitalis cannot be indiscriminately given in one and all types of heart disease. Recent careful studies by McCullough[8] based on electrocardiographic as well as clinical and pathological observations show that digitalis is contraindicated in diphtheritic heart disease with its widespread acute

myocarditis and conduction disturbances. Likewise in partial heart block, especially in the sclerotic high tension case, digitalis by its action on the vagus and His bundle, increasing the block, may precipitate Adams-Stokes attacks. The patient might die in one of the attacks, or on the other hand, the slow rate of a damaged heart may embarass the circulation to the point of heart failure because of an inadequate minute volume output. A clear conception of the disturbed mechanism as well as the pharmacologic action of drugs allows one to use digitalis for its diuretic effect and whatever effect it may have on the heart muscle, even in the presence of heart block. In this connection, the use of atropin in 1/50 grain doses once per day, and in any emergency makes safe the administration of digitalis to the point of getting beneficial effects.

The importance of the differential diagnosis of the disordered heart actions that may appear during a surgical operation or postoperatively, and are diagnosed acute cardiac dilatation, is obvious. The patient's life is often at stake or the maintainance of adequate blood supply in a part is essential to the success of the operation. If the paroxysm is one of auricular tachycardia, as it most frequently is, vagus pressure in 50% of cases will yield a spectacular cessation of the disturbance. If the paroxysm is of auricular fibrillation or flutter, rapid digitalization is effective or Quinidin may produce striking results with the establishment of normal mechanism.

Sinus bradycardia, sinus tachycardia, and extrasystoles require no specific therapy. The treatment of any presenting cause is indicated. An ice bag to the precordium is of service in any simple sinus tachycardia.

Auricular flutter and auricular fibrillation yield the most brilliant therapeutic results. Our ideas of these disturbances have been greatly changed within the past few years due to the work of Lewis and others[5]. The idea that the disorder once established, is ever afterward permanent has been modified by two notable exceptions, namely, the discovery of paroxysmal and transient cases, and the re-establishment of normal mechanism by Quinidin therapy in cases of apparently permanent auricular fibrillation.

The action of this powerful new drug Quinidin is explained by Lewis[6] on the basis of the existence of a circus movement in the auricular muscle about the great vessels, a single circulating wave propagated and revolving perpetually upon a re-entrant path sending out impulses at the rate of 450 to 600 per minute. The mechanism is possible only if (1) a circular path of sufficient length is available, (2) if the refractory period is sufficiently short, and (3) if the speed of the wave is sufficiently slow. Quinidin prolongs the refractory period and delays the recovery of the tissue, thus rendering the gap between the crest and the wake of the circulating wave shorter and eventually abolishing it altogether and normal mechanism, the sinus node, again resumes control. However, Quinidin slows conduction through the auricular muscle and this prolongs the gap and favors circus rhythm. This latter unfavorable effect acts exactly oppositely to the former or favorable effect, and when the unfavorable effect predominates fibrillation does not stop, but the auricle always slows from 400 to 600 down to 200 to 300, while the favorable effect stops the fibrillation. The rise in ventricular rate, which is quite frequently experienced, and often causes alarm, is due to the slowing of the auricular rate, which is conducive to less blocking. The paralyzing effect of Quinidin on the vagi is also conducive to an increase in the rate of the ventricle, although this is moderated in some degree by a direct depressing effect on the junctional tissues.

Following the methods of Frey[3] who has done the most work on this subject, we have used a preliminary test dose of 2 grains (.1G) to guard against idiosyncrasy to the drug. With no evidence of hypersusceptibility the drug was administered in 3 grain doses, gradually increasing to 7.5 grain (.4G) doses three times daily, the period of treatment totaling six to eight days. Occasionally larger doses were used and occasionally the drug was used over a longer period. Our results correspond to those of the many other observers in that in 20 out of 30 cases we were able to re-establish the normal mechanism. Our post-operative auricular fibrillation cases responded most uniformly and especially well when the etiology was toxic goitre or arterio-sclerotic heart disease. Recent cases responded most readily and most permanently. Cases of long standing were more refractive to treatment and more treacherous because of the danger of auricular thrombus formation during the long period of stasis. If there are any signs of cardiac failure, the patients should be thoroughly digitalized and, after suspension of the digitalis for ten days, Quinidin may be effective.

In cases in which auricular fibrillation has been established for some time, and where there are mechanical factors, as mitral stenosis, which tend to precipitate fibrillation, the disorder is often refractive to Quinidin. Even when Quinidin therapy is successful the reestablished normal mechanism is often of only short duration. Quinidin cannot be given continuously because it produces myocardial weakness. In spite of

the fact that normal mechanism is the most conservative, it is a question whether Quinidin is advisable in these cases in preference to digitalis.

Quinidin therapy is still in the experimental stage and not yet ready for widespread uncontrolled and indiscriminate use, for its administration is not entirely free from dangers. In recent especially post-operative hyperthyroid case the danger is least. Eventually it may be one of our most reliable and safe drugs. The intravenous use is not justifiable in the light of accompanying dangers. Cases presenting electrocardiographic evidence of defective conduction do poorly and sometimes terminate fatally quite suddenly. The danger of embolism from fragments of intra-auricular thrombi that have formed during the stasis and break on the re-establishment of normal auricular contractions, has been pointed out by Mackenzie and Orr[7], Benjamin and V. Kapff, Ellis and Clark Kennedy[7].

The striking and reliable effects of digitalization in auricular fibrillation and flutter are established facts. The type of digitalis preparation used, the method of administration, the dosage, and the criteria which determine the further management of these cases, warrant some discussion.

It is preferable to have a standardized digitalis preparation assayed by the Cat Method[4]. The Cat Unit being the weight of dry drug in milligrams, which is required to kill one kilogram of cat when the solution is slowly and continuously injected intravenously. High grade specimens of digitalis when not assayed by the Cat Method may be regarded as having an average activity of 100 mg. to the Cat Unit, but not more than 75% of the calculated total amount should be given in the first three doses. Likewise when the patient's weight is not obtainable, due to his poor general condition or generalized edema, estimations of the true body weight are to be made as accurately as possible and not more than 75% of the calculated total amount should be given in the first three doses.

The average total amount to be administered by mouth to man is 0.15 Cat Unit per pound of body weight. The calculation of the average total amount of the drug is then made according to the formula for the type of drug used[2].

$$\text{Grams of powdered leaf in total amount} = \frac{\text{Cat Unit} \times 0.15 \times \text{Weight in Pounds}}{1000}$$

$$\text{Cubic centimeters of tincture in total amount} = \frac{\text{Cat Unit} \times 0.15 \times \text{Weight in Pounds}}{100}$$

$$\text{Cubic Centimeters of infusion in total amount} = \frac{\text{Cat Unit} \times \text{Weight in Pounds}}{100}$$

With a standardized preparation, the average total amount for a man of 150 pounds is 2.25 grams (34 grains) of the powdered leaf, 22.5 c.c. (4.5 + fl. drams) of the tincture or 150 c.c. (5. ounces) of the infusion.

Pardee[9] gives a simpler method for estimating the amount of the tincture, which is the most widely used and most generally satisfactory preparation. He advises calculating on the use of 2 minims of standardized tincture per pound of body weight. For the man of 150 pounds this would allow 300 minims or 20 c.c. (4 fl. drams) of the tincture.

The method of administration of the total calculated amount is the next important point. Robinson[10] reported the use of the drug in a single massive dose with demonstrable clinical results, as early as three hours after the administration and always within 18 to 24 hours. For experimental purposes the single massive dose is advisable, but it is not entirely free from dangers. Eggleston's[2] methods are safer and very effective. When the patient has received no digitalis within the preceding ten days, in urgent cases 1/3 to ½ of the total calculated amount is given in the first dose. After six hours 1/5 to ¼ of the total amount, after the second six hours ⅛ to 1/6 of the total amount and every six hours thereafter 1/10 the calculated total amount until maximum digitalization. In non-urgent cases ¼ of the calculated total amount at each of the first two doses six hours apart and thereafter 1/10 to ⅛ of the calculated total every six hours until effect. If the patient has received digitalis within ten days and there are no evidences of effect, the total amount should be reduced to 75% of the total calculated amount. If there are evidences of partial digitalization it is safest to use not more than 50% of the total calculated.

The signs of digitalization are similar to those of slight digitalis poisoning. In auricular fibrillation, the auricular activity is not affected but through its action on the vagus the His bundle conduction is greatly reduced, so that only the stronger impulses at less frequent intervals are conducted. The ventricular activity is slower, more regular and more effective, so that with each ventricular contraction the aortic valve is opened and the pulse comes through to the peripheral arteries. The pulse deficit disappears, that is, the apex rate and the radial rate becomes similar, which is one of the results sought in digitalization. The drug is continued further until the apex rate is about 75, at which rate it should be maintained continuously. Nausea and vomiting after digitalization has

been under way for some days; a fall of the heart rate to 60 per minute or lower; and the appearance of frequent extrasystoles or a coupling due to bigeminy are signs of adequate digitalization and indicate a temporary discontinuation of the drug.

Digitalis therapy must be kept up in all cases of fibrillation. After digitalization, a patient will lose the digitalis equivalent of 20 minims, 30 to 40 drops, of the standard tincture per day. Consequently, to keep a patient digitalized with a heart rate at 75, he must receive this amount of drug daily. The effects of the calculated total amount are dissipated within a week to ten days, and therefore the small doses must be begun soon after digitalization. Thirty drops each morning or ten drops of the tincture t.i.d. are continued. After a week or so, the patient may again experience nausea, the drug is again temporarily withheld, and the dosage dropped to twenty drops of the tincture per day. The heart rate at the apex must be frequently counted as an index of effective therapy, which should keep it at about 75 per minute.

Along with the specific therapy, the general measures are most important, as Dock and others have long maintained. Rest in bed in Fowler's position, with morphine in full doses to promote sleep and complete relaxation are necessary adjuncts in the treatment of heart disease. A limitation of the fluid intake to 1000 c.c. (5 glasses) is of value especially in edematous cases, together with a low protein salt poor diet; all of these requirements are met by the Karell diet of 800 cc. (4 glasses) of milk only per day. An increase in the fluid output also aids considerable in cases of heart failure with edema. This can be done by the Hay concentrated salts method in which 5 to 15 grams (½ to 1 ounce) of Glauber's or Epsom salts, in not more than a half glass of water, are administered three times daily for five to seven days. Diuresis by theocin .2 to .5 gm. (2 to 7 grains) for three doses at three hour intervals in edematous cardiac cases that have had digitalis has been proven to be effective by Christian[1].

Massage, passive movements, resistant movements, and graduated exercises are rational methods of preparing a convalescent cardiac case for getting up and about and eventually back to work.

EPIDEMIC ENCEPHALITIS*

W. A. FANKBONER, M.D.
MARION

The individual symptoms of epidemic encephalitis are not new. They are classic in our knowledge of medicine. However, the symptom-complex and other clinical phenomena do not adapt themselves to the ordinary phases and progress of similar disorders, and this, together with the suspected epidemiology, permits us to speak of epidemic encephalitis as a new disease.

The characteristic features of the symptom-complex in a typical case arise out of the cranial nerve area of distribution. These nerves have their origin in the basal ganglia, midbrain, pons and medulla. The pathology as it appears in these parts is not new in its elementary characteristics. The only distinguishing feature of the pathology is that its intensity in the typical case is circumscribed in the parts of the brain mentioned.

What we know of this disease is not a textbook matter. Many of you have in mind, from your medical journals and from your contact with the disease, the data here presented. However, it is a matter of value that we at times review and discuss the things we have in mind and therefore I present this paper without apology.

My information comes from personal experience, case reports, and the current medical literature on the subject extending back over a period of about four years.

The following sources of information have been used: The Journal of The American Medical Association, Archives of Internal Medicine, The American Journal of The Medical Sciences, Journal of Laboratory and Clinical Medicine, Journal of Experimental Medicine, Medical Science—Abstracts and Reviews

*Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

—Oxford Press, Archives of Diagnosis, Medical Clinics of North America, Modern Medicine, Archives of Neurology and Psychiatry, Brain, Boston Medical and Surgical Journal, Progressive Medicine, Bulletins United States Public Health Service, Bulletin of The Johns Hopkins Hospital.

HISTORY: Inasmuch as we have allowed ourselves to speak of this as a new disease, let us go back into the history of medicine and see if diseases of a similar type have been described. There is evidence that, almost in the antiquity of medicine, Hippocrates described a type of disease simulating epidemic encephalitis. In Northern France five hundred years ago there was the "Picardy Sweat" characterized by great prostration.

In 1485 a type of illness appeared in London which, in three months, spread over all England. This epidemic followed closely upon the invasion of England by soldiers from the North of France. Five other English epidemics occurred down to 1551. Some of these were especially sevère, showing a mortality of fifty per cent. in some communities. People in all stages of life were stricken. It was not until this last epidemic that we have anything like a fair description of the disease. It is mentioned as of sudden onset, a sense of apprehension, shivers, chills, vertigo, pains in the neck, head and shoulders, prostration, sweats, fever, sleep; and fatal in two or three hours or a day. If the patient survived the first day it was assumed that he had fair chance of recovery.

In 1529 an outbreak occurred in Hamburg following the arrival at that port of the crew of an English ship. From Hamburg the disease spread over Central Europe, following the lines of travel.

In 1889-1890, following an epidemic of influenza in Northern Italy, Hungary and Central Europe there was present a disease of the encephalitis type.

In 1917-1918 epidemic encephalitis was reported from England, Central Europe, Australia, North and South America and Africa. Did the extensive troop movements of the World War have anything to do with this fairly world wide distribution?

Since the World War, epidemic encephalitis has been recognized generally. The first satisfactory recognition and description was by Economo of Austria in 1917; and it was he who put into medical literature the name lethargic encephalitis, but this name is now being superceded by the better one—epidemic encephalitis.

ETIOLOGY: An encephalitis may occur in the course of many infectious diseases, but this type of encephalitis is a secondary condition attending or following some other well defined clinical disease. Epidemic encephalitis is a disease entity. The clinical phenomena and symptom-complex are not secondary to any other well defined or predominating antecedent infectious process. It is true that the infection must find entrance to the body, and this likely occurs through the mucous membrane of the upper air passages, but this antecedent condition is insignificant as compared with later developments.

The evidence at hand indicates that the disease is not due to any of the well known infective agents or their toxins, and no etiological bacterium has yet been isolated. Some very valuable work has been done and it may be that the problem is well toward being solved, but as yet the results are not conclusive. Emulsion of brain tissue from fatal cases has been injected into rabbits, intracerebrally, producing characteristic symptoms and pathology. From rabbits the disease has been transmitted to guinea pigs and monkeys. The filtrate from brain emulsion will produce the disease if injected (in the rabbit) into the eye, sciatic nerve sheath, or when applied to an abraded nasal mucous membrane. The disease is not produced if these injections are made subcutaneously, intravenously, or intraperitoneally, or if inoculation is attempted by way of the trachea or stomach. Characteristic symptoms have followed inoculation with emulsion of naso-pharyngeal mucous membrane, and also by inoculation with the filtrate from such emulsion.

The disease is no doubt transmissable, but in what manner is not as yet well understood. By some observers it is believed that the virus is persistent and may be distributed by convalescents, or that attendants may become carriers without themselves showing symptoms, and that masked or abortive forms may be an equal or greater menace. The most likely primary focal area is the nasal mucous membrane, and the secretions from these parts are therefore the most likely sources of transmission early and late.

Data on epidemiology indicate a prevalence of the disease in the late fall, winter, and spring months. It is unusual for a second case to occur in the same family.

PATHOLOGY: The pathology is fairly distinctive and characteristic. However, the individuality of the disease from a pathological standpoint is not determined entirely by the character of the pathology but also by the circumscription of its intensity. This intensity occurs in that part of the brain embracing the optic thalami in the fore-brain and the cranial nerve nuclei in the mid-brain, pons and medulla. Not all the pathology is confined to this area. In all cases it is wide spread to a greater or less degree, and sometimes seriously invades the meninges cortex or cord.

Macroscopically the appearance is one of vascular congestion with hemorrhages into the white matter. These hemorrhages are petechial and sometimes larger. There is edema, and the brain tissue is more soft and doughy than normal.

Microscopically the small hemorrhages are brought out more clearly. There is cellular infiltration of the vessel walls into the perivascular spaces and into the white matter; proliferative changes, endothelial and interstitial, and degenerative changes in the nerve cells and nerve sheath.

The infiltrating cells are in the vessel walls, massed about the vessels in the perivascular spaces, and more sparsely scattered through the white matter. In some cases these cells have a tendency to group themselves about the gray nuclear areas, but these areas are not usually invaded.

The spinal fluid is clear and shows usually a normal pressure, a normal or only slightly increased cell count, negative luetic and negative culture tests. The pressure and cell count will vary in different stages—being higher in the earlier stages when the acute infectious process is most active.

The blood shows a moderate leucocytosis and negative Wassermann.

Culture tests in nerve tissue and in various other tissues show negative results.

The intraocular findings are usually insignificant.

The gray matter of the nerve nuclei being usually not invaded, then why the deluge of profound symptoms that we sometimes see that are referable to disturbed cranial nerve function? It has been suggested that the symptoms arise from or are accentuated by the mechanical conditions that are caused by the pathology in the brain stem. The lession in the white matter gives rise to pressure due to perivascular extravasation, edema and sometimes hemorrhage; and the nerve nuclei are easily affected by these combined pressure factors on account of their intimate admixture with the white matter in the brain stem.

The brain stem is not only the location of the various ganglionic nerve nuclei mentioned but through it pass all the conducting paths that come from the whole body in the spinal cord. Therefore the pressure factor of the pathology may have some influence on the manifestations in distant parts of the body.

CLINICAL PHENOMENA: Function derangement may be anything from a mild disturbance to a complete loss; different cases may vary widely in predominant symptoms; and the individual case will nearly always present distinctly new features as it developes.

Aside from the cranial nerve symptoms there may be hallucinations or delirium, suggesting a lesion of the meninges or cortex; or certain types of pain pointing to involvement of the posterior gray matter of the cord; or certain types of paralysis pointing to involvement of the anterior gray matter of the cord.

From a bedside study we will find that a majority of the cases have a prodromal period of a week or two characterized by asthenia, and in the latter part of this stage by diplopia, ptosis, and drowsiness. Other early symptoms may be headache and vomiting, which are likely toxic as may occur in any infectious disease. The diplopia will likely disappear in a week, but the ptosis continues; the drowsiness deepens into lethargy, and to these symptoms may be added a few or many of the symptoms that may arise out of the pathology described. This period may last from two to six weeks. The convalescent period may last over many weeks or months, and during this period the patient should have the most intelligent care and management.

It is difficult to evaluate the symptoms by any method of classification or enumeration, but to get a comprehensive view let us enumerate them as: (a) General symptoms: asthenia, drowsiness, lethargy (sometimes insomnia), stupor, coma, sweats, headache, vomiting, shivers, chills, fever, pains in the head, neck, arms and sometimes in the lower extremities. (b) Mental symptoms: restlessness, apprehension, hallucinations, delirium. (c) Motor symptoms: photophobia, diplopia, squint, nystagmus, ptosis, facial paralysis, mastication paralysis, tongue, throat and laryngeal paralysis, heart and respiratory disturbances, coarse tremors, choreic movements, spasticities, clonus, convulsions, ataxia, fecal and urine retention. (d) Sensory symptoms: various pains in the head, neck, arms and legs.

In the enumeration of these symptoms an effort has been made to cover fairly well the whole field of symptoms as they may appear in a series of cases taken collectively. Of all these, those appearing most uniformly are lethargy, diplopia, and ptosis—perhaps in seventy-five per cent. of the cases. The other twenty-five per cent. will tax our diagnostic skill. The predominant symptoms in these may strongly suggest other diseases, meningitis, brain tumor, poliomyelitis, etc., but if proper appreciation of minor symptoms is taken in such cases, and they are studied in relation to pathology we will arrive at a working diagnosis.

To make a more concrete picture of epidemic encephalitis I cannot do better than give the history of a case now under my care since January this year. This case is as typical and

presents as wide range of symptoms as any we are likely to see.

Mr. S., age 34, foreman in Stationary Manufacturing Co. History negative, venereal infection denied, blood Wassermann negative.

Jan. 22d, 1921, came to my office. General attitude and appearance of fatigue, slightly drooped eyelids and expressionless countenance. Had been seeing double for a day or two, eyesight slightly blurred. Five days previously he had slight nausea one day, not persistent. For a week he had been unusually fatigued, lying down immediately on reaching home. There was no pain of any kind, and was not during his whole illness. He took to his bed Jan. 23d and did not leave it for two months. He took no solid food for seven weeks after the third day in bed. During this time he could not masticate, and swallowed liquids very slowly and with great difficulty. For six weeks of this period he could not articulate any sound and most of the time made no sound whatever. From the latter part of January it was ten weeks before he could change the position of his body or turn himself in bed. He seemed to have no voluntary power in muscle action on account of spasticity. Twelve weeks from the time of taking his bed he was able to walk, showing some spasticity but no static or locomotor ataxia.

Before he took his bed an ordinary dose of magnesium sulphate gave good results, but from that time the bowels would not respond to any ordinary cathartic, but did respond to enemata. By the time he was able to walk the evacuations were without help and have been so since. This was the only symptom referrable to the gastro-intestinal tract. The bladder acted normally.

His general symptoms in order of incidence were: nausea, weakness, drowsiness, lethargy, shivers (at night during the second week—of sufficient intensity to shake the bed), temperature around 100 during the second week, some sweats but not profuse or persistent. The mental symptoms were only a mild delirium during the second and third week. His motor symptoms ran the whole gamut of the cranial nerves and into the long tracts of the arms and legs. These motor symptoms began very early and continued into convalescence.

His symptom-complex embraced asthenia, drowsiness, lethargy, diplopia, ptosis, a general opthalmoplegia with the flattened out blank expressionless face, inability to talk, inability to swallow anything but liquids, increased respiratory and heart rate, coarse tremors, spasticities, retention of feces.

There was not a full paralysis of any function. The spasticities were a uniform and persistent feature. If an effort was made by the attendant to open the mouth it was resisted by the masseter. If force was applied to change the position of an arm or leg there was a marked clonic resistance. The legs were in a constant slightly flexed position with the foot in partial extension. The arms were kept in a repose position across the chest in a fairly rigid state, the wrist and fingers slightly flexed. If the arm was lifted by assistance away from the chest it retained the flexed elbow and wrist and would remain away from the body unsupported until replaced by the attendant. Any voluntary motion that might be attempted by the patient was attended by a marked aggravation of the coarse tremor. The reflexes were all sharp during a period of four months. The diplopia disappeared within a week. During the next five weeks the grossly manifest cranial nerve symptoms disappeared and with them the lethargy. The spasticities disappeared in another five weeks. In four and a half months after the beginning of the illness light work was begun; but at this time, nine months, he is not able to carry the full load and there is no evidence to indicate when he will. The general body functions are good. There is now no objective evidence of the disease except a slight tic in the muscles of the left cheek.

DIAGNOSIS: This case presented no difficulties. It presented the cardinal symptoms: asthenia, diplopia, ptosis, lethargy. With these symptoms alone a diagnosis is justified—even with the mildest ptosis. One case coming under my care had no demonstrable diplopia but had the weakness, lethargy and a very mild ptosis without any other symptoms and was afebrile. He could easily be aroused but immediately went off into his lethargy and continued so for one month day and night.

The diagnosis must rest on some evidence of involvement of some part of that area of the brain which embraces the cranial nerve nuclei. This evidence may not be the predominating part of the clinical picture. Meningial, cortical or cord symptoms may be confusing. A case seen in consultation was at the time apparently one of general toxemia. There had been a temperature of 103 which had fallen to 100. He did not seem especially sick. Was dressed, lying on a cot. He had at times a mild delirium, more pronounced at night, and had trouble in sleeping. When approached in conversation he was rational. The diagnosis was determined by a later development of typical lethargy.

Another case seen in consultation could be termed acute paralysis agitans. It was in a man of such age as would be liable to this disease. The symptom-complex was typical of paralysis agitans but had developed rapidly and had a very early fatal ending, as one would consider mortality from paralysis agitans. I could not

keep from my mind the probability of the symptoms being a corallary to the main proposition of epidemic encephalitis.

In differential study there would come to mind, botulism, syphilis, poliomyelitis, brain tumor, cerebro-spinal meningitis, tubercular meningitis, uremia, alcoholism, hysteria, and conditions secondary to the ordinary infectious diseases.

The general diagnosis will call for a study of the following: (a) A usually short prodromal period in which may appear an upper air passage infection—also such symptoms as may appear with ordinary infectious conditions. (b) A characteristic phase in which may appear the classic symptom-complex, or a modified symptom grouping, or a decidedly confusing grouping of clinical phenomena that will challenge our best skill in differentiation. (c) Laboratory findings: blood count, spinal fluid tests, Wassermann and culture tests.

PROGNOSIS: By observers having to do with a number of cases the mortality is reported from nothing to forty per cent. The average is likely twenty. If the patient survives the early toxic stage he has a good chance for recovery. The two factors in mortality are the early toxemia and the affection of the vital centers in the medulla. Concerning the after non-fatal effects we will know more as time goes on and more convalescents are studied and reported upon.

This disease is an infectious process which may lead to a greater or less degree of fibrosis, both endothelial and interstitial, and to degenerative processes in nerve tissue. For this reason may we not expect to deal later with certain sclerotic processes, or some types of dementia or some types of chorea? The disease may produce an endocrine imbalance. Will this adjust itself?

I have seen but two cases showing after effects: The one reported, showing objectively only a slight tic spasm of the left cheek. This man tells me he is much deficient in endurance and cannot get the same interest and initiative in his work that he did before his illness. His mental processes are clear. Another case: A man, 36, never seriously ill, attack epidemic encephalitis Dec., 1919. First three days hallucination of a man in a lake trying to climb on floating log and never succeeding, no sleep these days, afterward lethargic five weeks, worked every day as shipping clerk in a paper house, at times while working walked into objects and against the wall on account of lethargy. He has been able to sleep but very little at night and none during the day since the lethargy left him. He goes to bed and after a half hour of restlessness lies awake the rest of the night in a fairly quiet condition with no special brain activity and without pain or distress. He came to me in March, 1921, presenting a general "let down" appearance. He complained of general fatigue and had some aching distress in the back of his head. His mentality was clear, the reflexes normal. He had been taking iodides, veronal, and trional. With 15 grains of the hypnotic he could sleep. The iodides were discontinued, the hypnotic reduced and finally omitted. At the present time, twenty-one months since the beginning of his illness, he is sleeping three or four hours a night. He has no pain or distress of any kind. His attitude is one of lessened interest in his environment. His mental processes are clear. His endurance is much deficient—not able to work.

TREATMENT: The treatment resolves itself largely into a question of management. In some cases in the earlier stages the nervous system is in a condition of stress and excitement—in most cases the condition is the opposite. In either type there must be an environment conducive to the minimum of shock to an already damaged nerve structure. The lethargy is not necessarily evidence that the nervous system does not receive impressions but rather that it does not voluntarily respond. Therefore in lethargic cases further damage may come from an irritative environment.

It is very necessary that there be a sensible understanding of the condition by the friends, a proper type of nurse, a subdued light and plenty of fresh air in the sick room, a nutritious and easily digested diet, plenty of fluids by the stomach, warm baths, proper bowel elimination and a limited drug therapy.

Several remedies have been used—hexamethaline perhaps more than any other, watching the kidney effect. Hexamethaline does find its way into the body fluids.

Serologic work has nothing definite to offer. However, it is shown experimentally that the injection of encephalitis virus into the eye of a rabbit, or the application of the virus to an abraded nasal mucous membrane will produce the disease; but will not do so if the rabbit had previously been given a subcutaneous injection of virulent brain emulsion. The serum of rabbits immunized by subcutaneous injection gives no protection to other rabbits against injections of virus into the brain. Neither does the serum of recovered monkeys or of recovered human beings have any protective action in rabbits. The serum of monkeys recovered from poliomyelitis does not protect against encephalitis, nor does the serum of encephalitis protect against poliomyelitis.

A matter of paramount importance is that the family and friends (and the patient as far as possible or advisable) shall have a proper

understanding of the disease and the course it is likely to pursue through a period of many weeks or months. In this way only can that proper cooperation be secured which is so essential in carrying out the plan of management.

DISCUSSION

DR. CLAY BALL (Muncie): I wish to mention the so-called mild or abortive cases, in which there is no localizing disturbance, when you find no cranial nerve pathology to help you in the diagnosis and the constitutional symptoms are your lone symptoms. You have early a slight febrile reaction, with a little lethargy, which is profound and lasting. This lethargy is too profound to be attributed to any toxic condition of which we are aware. The patient does not seem to be sick, he is ambulatory, and the lethargy is out of all proportion to the constitutional symptoms. That is one thing which has impressed us with the thought that we have met something new. These ambulatory cases, from the standpoint of public health, are frequently the worst cases, for they are the hardest to isolate. You ask if it is necessary to isolate them. Certainly very little has been said about this, and we know that the contagious element is very small, but basing our idea on what we know of other infectious and contagious diseases it seems that we should isolate these patients. If we do not isolate we do nothing. Flexner has called our attention to this and many states require that they be reported.

There is another class, the severe type of the fulminating type, which attacks the patient very abruptly. I saw one patient with one of the leading neurologists of the state, and he died within a few hours. Another case, after four or five days in convulsions, finally got well. This man had two spinal drainages and on regaining consciousness proceeded on his way to health. I cannot say that the spinal drainage had anything to do with his recovery, but it is at least a coincidence. Other men have noted this fact.

DR. GEORGE F. BEASLEY (Lafayette): We had an epidemic of this disease in my town in 1872, and called it "spotted fever." The head would draw back and there was a curve to the back. I started in with bromid of potassium and it did no good. I remembered I was taught that in inflammation of the serous membranes you should give opium until you produce an effect, so I started in with a little, about one-twelfth grain, and the only relief the little patient could get would be for his big brother to sit alongside of him and keep a pressure with his hand on his head. The only thing he could keep on his stomach was crude opium. Morphine had no effect. I finally ran it up to one grain, then to two grains, and told the parents to give it every hour until he was easy. Then I said, "The old lady will probably give him too much and he will die, but at least he will die easy." When I came the next morning I did not see any bed hanging on the fence, as they always did in those days when anybody died, and when I went into the house the patient looked up and said, "Good morning, Doctor." I asked how many powders they had given him, and the mother said that they gave him two teaspoonfuls at midnight. A week or two afterwards I read an article by Jacobi in which he said to give opium until you get an effect and then I felt better. Since then I have given such patients opium, kept the bowels open by enemas and by salines, but have never put an ice pack on the head.

DR. CHARLES F. NEU (Indianapolis): It is a source of gratification to find this subject brought before this section. The condition is serious from a number of standpoints. First, because of the insidious onset in so many of the cases. Second, because of the difficulty in diagnosis. Third, because of the inability to carry out any definite line of treatment. Fourth, because of the serious after-effects. While it is true that a great many cases in their onset are acute and definite, in that you have definite loss of function of certain activities of the nervous system, such as cranial nerve paralysis, as has already been referred to, there are other cases in which the symptoms are not so definite. It may be said that there is not a symptom manifested in this disease that does not occur in other diseases of the nervous system—that there is nothing pathognomonic. There are certain things that make the diagnosis suggestive, but taking the symptoms individually there is nothing pathognomonic, and the difficulty in the treatment is in not knowing the cause. The filterable virus has been isolated and inoculated with reinfection, but no definite isolation of the bacterium or animal organisms, such as we are able to isolate in tuberculosis, etc., has been accomplished. The diagnosis has to be made by elimination. You have to eliminate other causes and fall back on epidemic variety unless you have the definite symptom-complex to start out with. The particular group of symptoms that is manifested depends upon the particular part of the nervous system that is predominantly involved. In many cases there are mental symptoms which are predominant—sleeplessness, delirium, hallucinations, and even definite psychoses, such as mania and paranoid conditions, may be the predominating signs.

DR. CHARLES D. HUMES (Indianapolis): I wish to say that the great number of cases I see do not come to my attention until after the toxic

effects have worn off. I have seen them after eight or ten months still manifesting the choreiform movements, partial paralysis and mental disturbance. I think rather than try to make many classifications of encephalitis we should classify them under one head. I wish to repeat what has been said that any symptoms which occur in any organic neurological case can appear in epidemic encephalitis. No examination is complete without a most minute study of the fundi, the visual fields, and the serology. I have in mind a case which I studied with Drs. Neu, Whitaker and Eberwein, where the man had stupor, ptosis, partial rigidity of the pupils, mental defect, and asthenia. *The fundi were quite normal but he had a complete* left sided hemianopsia and the postmortem revealed a mixed cell sarcoma of right brain. I mention this because in our efforts to diagnose from a few symptoms we should explore the whole neurological field.

DR. L. D. CARTER (Indianapolis): There is one point I would like to emphasize and that is the value of spinal puncture in the acute stage of the disease. In the treatment arsenic is the only drug that seems to give any benefit, but in my cases I think the ones in which we have used complete and frequently repeated drainage of the subdural space have probably gotten along better. The spinal fluid findings are not characteristic. There is occasionally an increase in the cells and in globulin. The amount is not much increased. On puncture it first comes with a spurt and then settles down to a steady flow, showing that there is not an actual increase in the fluid, but a swelling of the brain and cord, with pressure on the subdural space. I have cases who have suffered from this disease two or three years ago and who still show disturbances, either motor, sensory or mental. The prognosis is difficult. I think complete recoveries are rare. There is almost always some residue for months or years after the attack.

DR. ALBERT E. STERNE (Indianapolis): I do not believe that there is such a thing as a primary nervous disease. To my way of thinking the nervous system is practically always secondarily affected. As long ago as 1835 or '40, Semerling called attention to the fact that the pathology of "poliomyelitis acuta" lay in the vascular system primarily. Many years after this, von Leyden called attention to the fact that certain clinical syndromes were found, which formed clinical and pathologic related entities. Von Leyden showed that true bulbar palsy, subacute bulbar palsy, chronic poliomyelitis, commonly called "progressive muscular atrophy" and the form associated with amyotrophic lateral sclerosis were one and the same thing; but different segments of the nervous system are involved, and therefore there are certain differences in the clinical manifestations of disease, but they are essentially the same thing.

Let me emphasize that you cannot ever rely on any single symptom. Probably all of us have been impressed by the fact that there is a distinct resemblance in cases of epidemic encephalitis all the way through, to certain well known medical pictures, which we have seen for many years in the more isolated forms and in epidemics such as we saw, the older ones of us, after the influenza epidemics of 1890 and '91. Especially in the one of 1890 the nervous system was extremely involved. The association of nervous symptoms along with certain manifest infections, a certain selective action on the neuraxes which is taken by certain unknown invading agents, such as we see in poliomyelitis cases, is not at all uncommon. This selective action is clearly demonstrable in epidemic encephalitis, but the disease must first of all be considered a general constitutional infection. The central nervous system is secondarily involved by way of the vascular system, the usual mode of invasion, not only in epidemic encephalitis, but in epidemic poliomyelitis, epidemic meningitis and other similar affections.

Undoubtedly many cases have been erroneously classed as epidemic encephalitis; on the other hand many mild or undeveloped forms have been overlooked.

I regard the prognosis as very grave as to complete recovery. A tardy, tedious recuperation must be looked for, even in the most favorable cases.

DR. W. A. FANKBONER (Marion) (closing): I have not much to add, but I appreciate the reception given the paper, and the very intelligent discussion. I think one great satisfaction to an essayist is what he can contribute to general medical welfare. I do not mean necessarily anything new, but if what he says can stimulate a discussion and out of that discussion there comes a reiteration and emphasis of what we already know, or some new suggestions, that is of value.

One of the things that I think needs emphasis is what Dr. Sterne has mentioned, and that is that this is not a local disease. There is no disease of any type whatever that is entirely local in its pathology, in its symptomatology, or in its after effects. So with this disease, the infection must find entrance to the body through some local area, and in some inscrutable way which we do not understand the brain stem later suffers most in typical cases; and, as Dr. Neu has emphasized, the brain pathology is not all of it by any means. The pathology is widespread and in some instances it is not the brain stem but some other part of the nervous system that is most severely attacked.

To me the great interest that comes from a modest effort of this kind is the great value that the study of current medical literature gives us and the great value of the collateral information that goes with the study of any pathological process and the clinical phenomena arising out of it. It is not that one has written a paper and presented it, but that through such an effort some benefit has come to our honorable medical profession.

SOME PROFESSIONAL SHORTCOMINGS*

WILLIAM A. HOLLIS
HARTFORD CITY

I wish to thank you for the honor of having made me your Chairman for the year just closing. I realize it is my duty and a privilege, as such, to fulfill that obligation as best I may and to bring to your minds topics that are not new to you, but which to me seem worthy of consideration. There are problems, other than those of scientific interest, that confront us as medical men.

I shall not attempt to solve them alone, but will cooperate with you, now and always, for the betterment of our profession and its honorable recognition by minds that are yet in the grasp of pathies and cults.

CHIROPRACTIC

Like Knighthood, which was once "in flower," chiropractic is now "in full bloom." All other cults have gotten their vertebrae out of "alignment" and their nerves "impinged," for the time being at least.

Who would have thought, a few years ago, that such a hoard of uneducated craftsmen, with only a few weeks of training, could develop into such automatic puppets, working so harmoniously and in unison with the brains of their promoters? There should be a lesson in this to us. As soon as the petals of this flower have fallen, other varieties will be budding.

If people will fall for, and become enthusiastic over, a fantasy, how would scientific truths appeal to them if presented properly? If the success of such an organization depends upon a few shrewd, well paid propagandists and advertising managers, why cannot we adopt a similar method of influencing the minds of the masses?

We have learned the lesson, in this State, at least, that legislation does not control. We can do very little, working alone, to influence public opinion. Our disgust for the cult sometimes brings us into conflict with the mind of a faithful disciple, and we get no further in the end than a tirade upon this individual for being such an intellectual nonentity. Nothing is accomplished by such antagonism.

"The public press is a moulder of public opinion, and if the regular medical profession had taken advantage of the public press in making the public acquainted with the accomplishments of scientific medicine, the public would not today be suffering from the effects of so much quackery and charlatanism."—(*Jour. Ind. Med. Assn.*, Sept., 1921.)

The propaganda and reform department of the A. M. A. should reach further than enlightening doctors about things they already should know. It is the people who should be reached.

We of the medical profession are largely to blame for the situation, and we are the ones who will have to take the initiative in eradicating these pests. How many of you would enjoy practicing your profession in a state where the chiropractors and osteopaths are legally qualified, through their own separate Boards? It is almost unthinkable, but such is the case in Oklahoma just recently. Shades of Æsculapius! our brethren out there must be in a happy frame of mind.

CONSULTATION

Consultations with our medical friends, as a personal favor and for unselfish scientific interest and helpfulness, is one of the splendid ways of strengthening fraternal bonds and learning from each other. We should consider it a high compliment of friendship and confidence to be asked by a colleague to assist in the examination of his patient, that some phase of the situation may be cleared up. You certainly are keeping a friend, and the greatest good is being done for the sufferer. We should never place a financial value upon such consultations. Our medical friends should feel free to consult by phone, on the street, by letter, or call at the office with his patient, without embarrassment or apology. I hold in the highest regard you men to whom I have appealed from time to time for advice and counsel, and which was so freely given. I have in my files a mass of correspondence which has been extremely helpful. As we learn from others, so should we also learn from ourselves. This may be done by taking a serious interest in our work and keeping a check-up on it. Carefully written case records should have been begun long ago and should ever be continued. Do not trust to memory or become satisfied with an easy going routine. Besides the helpfulness to yourself, a most favorable impression is created upon the minds of patients that a genuine interest is being taken in their cases. Nothing is more humiliating than to have to ask a patient what his trouble was or "What we did for you when you were here before." We

*Chairman's Address before Section on Ophthalmology and Otolaryngology at Indianapolis session, September, 1921.

either push ahead or slip backward. There is no professional nor intellectual level. Go back over your old case records occasionally and see how much you have forgotten, how your work has improved, or perchance fallen short. In this way we learn from ourselves.

REFRACTION

There is, sad to say, a lot of eye men who are doing the poorest sort of refraction. For this situation there is no excuse. If they do not know how, they should learn. Take the time, care and interest and charge for it. I know personally a few men, members of our society, who have been influenced so insidiously by the commercial methods of some opticians, that almost without intent and at first reluctantly, they have partly given up the only dependable method of refraction that has stood the test of time in the hands of masters in our profession. It is positively absurd to think of abandoning homatropine, hyoscine and atropine, when indicated, regardless of the age of the patient, because of the whims, caprices and prejudices of the misguided. We may as well compromise scientific medicine with chiropractic. Take advantage of the tirade against it by the pseudo doctor-optician, who is quite often a chiropractor on the side, to do better work and gratify your ideals and convictions with a better and more intelligent class of patients. I have done this and I hope you here today are doing the same.

While there will always be more refraction to be done than there are oculists to do it, and well-trained, conscientious refracting opticians—as well as ignorant pretenders—will be in demand by the masses, the facts remain that ametropia and its results must be recognized and given serious consideration. A vision 20/15 does not necessarily mean that there is a perfect physiological working. Many most serious diseases may be present.

Let us visit and learn from each other occasionally. Call on your professional friends at home and away—see their work and compare your own with theirs. They will be glad to tell you all they know.

By way of digression, permit me to mention a little, but very important, thing I picked up from a friend whom I see before me. I noticed that he used a perforated disc, with an opening about the size of the average pupillary diameter, before the eyes that had been prepared for refraction by cycloplegic. The purpose so apparent, the thing so simple; so essential to clear, sharp central vision. All confusing peripheral rays shut off, as in an eye where the accommodative and pupillary reflexes have not been abolished. From then on, I have done no refraction without it and I get better results. Try it both ways and convince yourself, to your own satisfaction. This is one example of practical, accidental helpfulness.

SYPHILIS

We should ever keep before our minds, as do the internists and general practitioners, the frequency of syphilitic infections and their complications. Do not work alone in the management of these cases. In the treatment of syphilis, we have learned a lot when we realize that our friends who sent us these cases know more about its management and treatment than we do, as a rule. We know more about its effect upon special sense organs than they, and it is for that aid alone we are solicited. I do not want to be misunderstood as saying that we wash our hands of responsibility by so doing. Lazy, incompetent and conscienceless practitioners are to be found in most all communities, but there are always good men, to whom we owe a debt of cooperation and confidence. Without having needed our assistance, the case would not have been referred to us, and when our work is done the patient should still be in the hands of the one to whom the case rightfully belongs, if he is prepared and willing to continue treatment. In other words, the medical men will have a greater respect for us if we do not administer our own salvarsans, if we can avoid it. Group practice, in this modified form, is practical in every community. We should not and cannot work alone. What applies to the management of syphilis also applies to other conditions which call for aid and cooperation of internists.

TURBINECTOMIES

You here today are not in the class of turbinate barbarians and cannibals. We still have them with us, though; the legalized, mercenary, conscienceless near-quacks, whom we have not been able to reach. They hide themselves and we see only the "works of the devil." How helpless we are and how we pity the poor, innocent victim, the possessor of a wide open nose, dry, scabby or perhaps a fetid ozena, when we behold a nasal septum as crooked as the coast of the New England States and the turbinates destroyed on the false assumption that an air channel must be secured no matter what means employed.

If you cannot do a good submucous resection, for Heaven's sake leave it alone or have someone do it who can.

TONSILLECTOMIES

The tonsil, like the appendix, has been the object of jest, ridicule and scepticism, to a greater or less degree, by both laymen and some physicians. Sometimes it is remarked by a patient that "My doctor does not believe in tonsils"—as though it were a religion or a creed. He may not believe in "worms" either, but that

does not alter facts. I think after all that this influence results in good, for it acts as a check upon our enthusiasm, causing us to stop, look and listen. However, more tonsillectomies are being done than formerly, and will continue to be. But, like the wholesale and reckless sacrifice of teeth, their indiscriminate removal has given cause for a protest of conservatism that is having a favorable influence. We will have to say that, if there is any doubt as to whether or not a tonsil is feeding organisms and toxins into the blood stream, or harboring organisms of a dangerous kind, their removal can do no possible harm, if properly done. To my mind this brings up an important consideration.

How many of you have a definite and reliable technic for any and all kinds of tonsils in this operation? If you have none, it is time you were developing one. At every meeting of the State Society and other gatherings we see a great array of new-fangled instruments for tonsillectomies, or mostly some modification of a freakish device. When we meet our friends at times, as we do here today, among the first question asked is, "What method of tonsillectomy do you use?" Your reply should be, "A strictly surgical enucleation," rather than naming some man in St. Louis, Cincinnati, Kansas City, New York or elsewhere. The whole outfit should be dumped into the rubbish heap as non-essential, fantastic and unsurgical contraptions. There would then be less temptation for the untrained.

We who pose as skillful men in our chosen field, do not always do an ideal enucleation, with a minimum of traumatism and resulting scar tissue, but we should be more dependable than one who does them only occasionally. When we seldom, or almost never, leave a mass adherent to a patch of capsule, or mutilate the pharyngeal pillars, we will have a greater respect from some of the general men who have discovered that they can do cleaner work than some of us. I am sure none of us have any right to complain of any one in general practice doing his own tonsillectomies if he does them well, for he may have discovered that his results are more satisfactory than the surgical colleague in his community.

None of us are 100% perfect. Some of you have seen a fragment of tonsil left by me; I have seen the incomplete work of some of you. Let us be charitable. When such is discovered, do not make it an occasion to create prejudice against the work of one of your friends who, on the whole, may have greater and more dependable skill than his critic.

Don't sit around and worry about the men in other fields who are intruding our sacred domains, without first inspecting yourself. The fault may be your own. Cut out your general practice and all surgical side-lines, play the game fair and they will support you, almost to the man, everything else being equal. Neither you nor they can succeed well, professionally or financially, with too many irons in the fire. The same may be said of some general surgeons, who do a little of everything because they need the money, as they frankly admit. In the end they do not get it, and I have never seen one of them get far. To maintain their dignity, to keep the confidence and respect of doctors and laymen, is inconsistent in such practice. If you are an Opthalmo-Oto-Rhinologist, be one; if a General Surgeon, be one.

MEDICAL MISFITS

There are two classes of medical men who are not helpful and are hard to assimilate. They will not cooperate and are an absolute hindrance to progressive medicine. These are the medical broker and the medical croaker. The first is one who is out for gain at any cost, regardless of hardships and inconveniences to fellow-beings. He takes much but gives little. He cares nothing for public opinion in matters of equity and community welfare, or professional advancement; cares nothing for what you think of his methods. He is aggressive, domineering, hypocritical, pretentious and strutty; a friend to your face, a traitor to your back. Meet him in consultation, he is the chief actor, working well up-stage. When you depart, he will remain or return and take advantage of your absence. Meet him alone and he is suspicious. Crowd him into a corner, you will behold a frightened, trembling, apologetic, cowardly crook. Better get him then, or he will try to get you later. He belongs to most of the medical societies, but never attends; does not permit his dues to become delinquent for reasons quite obvious. Avoid him. His selfish ambition has hardened his heart. You are better than he and he knows it.

The medical croaker—he neither hinders nor helps. He would not be missed, yet you wish him no harm. What the majority are for, he is against. You are in the wrong, he is always in the right; never succeeds well and admits it, but it is not his fault; takes no part in discussions at society meetings, but does a lot of barking and criticism in private; makes a great fuss and flurry about weak medical laws and wonders what is the matter with the profession, but does nothing himself but rant.

He is strong on the laymen, but weak on the medical brethren. Belongs to no medical societies—the A. M. A. is a trust; prefers proprietary medical literature to standard medical journals; profane against quackery, but will sign a death certificate for a chiropractor.

Don't be a broker. Don't be a croaker.

DISCUSSION

DR. E. M. SHANKLIN (Hammond): One thing that Dr. Hollis said that struck me particularly is the management of luetic cases that come to the specialist. There are, in Indiana, I take it, a few men who are fully and competently equipped to personally direct the treatment of lues. But there are so few of the Indiana eye, ear, nose and throat men who come under that classification that as a general rule I should say these cases, in all fairness, should be referred to the internist.

That leads to another suggestion: We depend to some extent on referred cases coming to us from the general practitioner, and yet too often are we prone to forget the source from which these cases come. I will refer to just one specific instance. A case is referred to a specialist for a tonsil operation. The routine examination of the patient develops that there is an albuminous condition of the urine. I happen to know that there are specialists who will undertake to correct this condition of the urine, notwithstanding the fact that the case has been referred directly from the family physician of the patient. I believe such practice is wholly wrong. I do not believe that any man doing eye work has a right to undertake the treament of a nephritis. They should in all instances be referred back to the man who sent the case to you.

DR. O. C. BREITENBACH (Columbus): Only one word with reference to a hybrid that the profession harbors. I refer to the man, who, because of his lack of knowledge of present day medicine, and judging his confreres' ability by his own, apparently in sheer desperation refers his wife or children to a chiropractor in the community when his feeble efforts are incapable of stimulating feelings indicative of returning well being.

I also have in mind that species of practitioner who hovers nigh to the optometrist, seeking his favor, and finds it justifiable to refer eye work to him in hopes that the optometrist will in turn refer nose, throat and ear cases to him.

We come in contact with this individual in every community, and I, personally, feel that the man who has no more regard for the sanctified portals of regular medicine than to allow the pollution mentioned, ought to be a discard of legitimate medicine. An innate sense of self respect ought to hold the legitimate medical man in his own chosen field. The base interests of the optometrist and chiropractor are thus fostered by this individual whose main object in carrying out a public trust should be the branding as vicious the influence of all cults of this description.

DR. C. J. ADAMS (Kokomo): My county society has appointed a Publicity Committee to tell the community what we are trying to accomplish. We are not aiming to fight the chiropractor or the optician, but we are aiming to let people know who and what the medical profession is composed of, and just exactly how much time, work and expense the medical man has been put to to gain his education; just what his ability is and what he can do and is doing. We haven't gotten the thing to working yet. I don't know of any other medical organization in this state that is doing anything of the kind. I believe we are going to chase some of the quacks out of our community.

DR. W. A. HOLLIS (closing): The main idea is to cut out commercialism, be progressive, play fair, do the right thing, and remember that we all live in glass houses; be on the square, practice your specialty, and, as I said, don't try to be a Jack of all trades.

Remember, you have colleagues who are your friends, and they reach beyond the confines of our specialty. We have to work with them, and we can accomplish nothing without their aid.

"THE PHYSICIAN"

MYSTICISM AND SYMBOLISM IN RELATION TO THE HISTORY OF MEDICINE*

By
FRANK B. WYNN
INDIANAPOLIS, INDIANA

A consideration of mysticism, medical symbolism and history suggests to the average physician's mind something very remote and unrelated to the present. His thoughts go fleeting through the centuries to the distant past of the ancient Assyrians and Chaldeans; to the early Egyptian dynasties; or to the less remote medical mythology of the Greeks. It does not occur to him that despite the progress in fundamental science and the practical arts of civilization, the refinement of medical mysticism in those ancient days puts to shame the crude practices and beliefs of our own time. One may learn medical mysticism from the "Medicine Man" of the Black Feet Tribe in northern Montana; or at the annual snake dance of the Hopi Indians in Arizona. It is exemplified in the common buck-eye carried in the pocket to ward off rheumatism; or the mad-stone of famed value when applied to the bite of a rabid animal. Its superstitious influence is apparent daily in the precious stones treasured or the jewelry worn. It speaks powerfully in many who look askance at Friday and the number thirteen, and in the farmer who plants by the signs of the moon.

*Nineteenth of a series of articles by Dr. Wynn which will appear regularly in THE JOURNAL.

These are familiar illustrations of individual customs and beliefs in our own day, showing how deeply ingrained into our inherited nature are the influences of superstition. If more magnificent examples are sought showing systematic and widespread organization in support of mystical healing, one needs but turn to the splendid Christian Science Temples to be seen in every city, where the reality of the senses is in large measure denied; whose "healers" claim divine influences, even alleging cures by "absent treatments." Strange as it may seem at first thought, there is a striking similarity between the ancient Greek Temples of Aesculapius and these modern edifices devoted to mental healing. At one time these temples scattered throughout Greece numbered over three hundred. Like the "healers" of the Eddyites today, they claimed supernatural power. In time of epidemics, the priestess or goddess Hygeia, would come forth, in her hand waving the serpent, emblem of healing, over the multitude. Thus all were blessed and supposedly the afflicted were healed or the well protected against evil influences causing disease. Eddyism, however, is only a poor second edition of ancient Aesculapianism, for the latter whilst assuming the exercise of supernatural healing, wisely sought the aid of natural forces as well. Accordingly the Temples of Aesculapius were located with extreme care, having due regard for the charms and healthful benefits of the outdoors. As the sites of these institutions they sought refreshing groves, the purest mountain air, the most brilliant sunshine; pure lakes and streams and health-giving springs. They were in truth the first Health Sanatoria. From the priestess or goddess (Hygeia) of the Aesculapian temple has come down to us the modern word *hygiene*. Thus it is seen that Eddyism is nothing new, in fact only a reversion to ancient medical mysticism, but without its chiefest virtues.

If study be made of any race or tribe of people in their early evolution it will be found that religion and medical practice go hand in hand. It was true of the ancient Chaldeans, the early Egyptians and the Greeks as it is true of barbarous tribes and healing cults in our own generation. Superstition and mysticism pervade all medical beginnings. A very natural outgrowth of evolving medical mysticism is medical symbolism. A symbol is some material thing which stands for an idea, a principle, a creed. Most symbols typify aspiration for better or more glorious things. Some however stand for baser thoughts and designs, as the saber of Mars betokens a bloodthirsty purpose. The Old Testament scriptures are built upon symbolism. Under the New Testament regime the Mother Church perpetuated symbolism in modified form and elaborated it to a point where revolt came in Protestantism. The very heart and brain of the Masonic order is symbolism. The human mind is so constituted that it craves representation of its ideas and ideals in symbols.

Since scientific methods have separated to a large extent the mystical from the medical beliefs and practices, symbolism has had small place in medicine. What remains is not to be construed as inconsistent with scientific ideals. As scientists loving the truth we can do naught else than turn with sympathetic interest to the struggles of our profession to emerge from superstition and barbarism. If certain symbols come down to us from the ancient days, let us view them with genuine historic reverence, as representing phases of evolution toward a higher civilization.

The eagle is the most ruthless murderer of inoffensive birds among the feathered tribes. As such we detest and abhor its rapine. But on top of the American flag-pole, as a symbol typifying aspiration and liberty we idealize it. So in medicine, the symbols which tradition, mysticism and history have passed down to us are interesting as standing for the evolution of science; and we may be pardoned for perpetuating them as symbolic of the good and true, from whatever age derived. As physicians it is well that we know something of this symbolism and its suggestive meaning.

Most symbolic representations bear the mark of oriental origin. True they have descended to us through the Hebrews, the Egyptians and the Greeks. The symbolism of the Greeks always had an eye to curved lines, the grace of form, color, symmetry—in a word, beauty, Not so with oriental symbols which stood for an idea, a principle. For example, the ox typified patience; the serpent, wisdom and prudence; the eagle, aspiration.

In approaching the subject of medical symbolism only the briefest references need be made to Greek Mythology. Apollo, the sun god, and worshipped as the god of medicine, is said to have derived the power of divination and healing through the slaying of the serpent Python. Aesculapius was the reputed son of Apollo. Homer records in the Iliad that Aesculapius went upon the Argonautic expedition. So successful was he as a physician that Pluto became envious and complained to Zeus who slew him with a thunderbolt. At the request of Apollo he was placed among the stars. Hygeia was the daughter of Aesculapius and the high priestess of the temples which bore his name. Thus it is shown that medicine had a most noble mythological lineage. It was from this heroic period in early Greek history that most

of the medical symbols sprang into common use, although their origin must be traced in most instances to the Orient.

The most ancient and generally employed medical symbol has been the serpent. If study be made of almost any race of people, it will be found that in their primitive period the serpent appeared as the emblem of wisdom and healing. It was true of the Assyrians and Babylonians, the Egyptians, the Greeks and even the Mound Builders of America. The American Indians of the present day exemplify the same fact in their snake dances. This curious truth would appear to point to the common origin of mankind. Serpent worship prevailed in the Orient. The serpent was considered sacred, and stood for prudence, health and immortality. Its emblematic significance of health and life no doubt came about through the fact that each year it was revived from a state of lethargy and its skin cast off—typifying to the mind of the Oriental seer, return of health, new life, resurrection.

In the birth and growth of the Hebrew religion the serpent figures largely. While in the fall of Adam and Eve it stood for evil, it was not always so. When the Children of Israel were being led out of Egypt through the wilderness by Moses, it is recorded there were murmurings, whereupon the Lord sent fiery serpents among the people, which bit them. Moses prayed for them. Then the Lord commanded him to make a fiery serpent of brass and hoist it upon a pole and directed all those who had been bitten to look upon this image and they would be healed.

It was almost four hundred years after the time of Moses that Aesculapius and his followers dominated Greek medicine. Whilst he, like Homer, is catalogued in the mythological realm of Greek History, there certainly must have been some such medical personage of extraordinary personality and genius. He and his followers initiated the movement which brought medicine out of the darkness of mysticism into the light of scientific methods, under Hippocrates. Their teachings, such as they were, evidently made a tremendous impression upon intellectual Greece—apparent even in Hippocrates himself, as well as in the great philosopher Socrates. In the realm of Grecian Art also, Aesculapius occupied a prominent place. Statues of him decorated most of the temples of healing. The one at Epidaurus is most familiar to us because it was brought to Rome in 292 B.C. to avert pestilence. It remains today in the Louvre as a precious heritage of early Greek art.

From a study of these statues much of our present knowledge of medical symbolism in early times is obtained. A wreath of laurel is upon the head indicative of the high esteem in which medicine was held. The dog was frequently associated, typifying the watchfulness and faithfulness of the physician. The cock was another significent emblem. On the one hand it stood for sacrifices in the interest of the suffering; and on the other represented the sacrificial offering generally made by grateful patients for their restoration to health. This custom was beautifully shown by the dying philosopher, Socrates, in the following dialogue: "Crito, I owe a cock to Aesculapius; will you pay the debt?" "The debt shall be paid," responded his friend.

Some of the Aesculapian statues represent the extended hand, holding a fir-cone. Like the serpent, this medical emblem is of Oriental origin. The "Tree of Life," from which it was obtained, was sacred and guarded by priests. To the minds of the ancient Assyrians and Babylonians, the fir-cone possessed the power to repel demons and impart "the breath of life."

But most constant of all the Greek symbols of medicine was the Staff of Aesculapius. The story of its origin is told in the Iliad. One day when on the Argonautic expedition, Aesculapius sat in his tent treating Glaucus. A snake entered and entwined itself about his staff, thus endowing him with wisdom and prudence. Ever after it was his constant companion in his labors. The Aesculapian staff adorns the badge of the American Medical Association, and is worthy to be accepted as the world-wide symbol of our profession.

Curiously, almost unaccountably, the *caduceus* or Wand of Mercury (Greek, Hermes) has been permitted in modern times to usurp the place of the Aesculapian Staff as a medical emblem. Its use became so general, especially during the world war, that it appears doubtful if it will ever be displaced. It will be recalled that Mercury was a messenger of the gods—indicated by the wings on the staff. In ancient times the *caduceus* was the badge of neutrality, of commerce and trade—the arts of peace as opposed to the destruction of war. Upon the wand the serpents do not stand for wisdom and healing, but for peace. This is indicated by the traditional story concerning the birth of the *caduceus*. Mercury came upon two snakes fighting, whereupon he smote them with an olive branch received from Apollo. He was surprised to find them cease contention and become friends. If we dared modernize the ancient interpretation of the *caduceus*, very fittingly the wings might typify messages of scientific and spiritual truth from on high; and amongst professional colleagues the serpents might stand for a mutually helpful peace; and on earth good will to men.

A very interesting group of medical symbols should be considered separate from those which have preceded—the talismans and amulets. As we know them, they were the product largely of ancient, oriental mysticism. Few persons realize that many of the ornaments worn upon the body for personal adornment, trace their birth to very ancient mythology. Originally they were worn as charms, supposed to possess magic power to avert evil influences and preserve health.

Talismans owed their birth to astrology. Why should we marvel at this? What a soulless creature is he who in the solitude of night can gaze at the star-lit dome without a thrill of wonderment or the yearning to know and understand it all? With the very beginnings of intelligence in the human race, came the star-gazers. Out of their efforts grew astrology. Even the noted Roman physician, Galen, wrote extensively upon this subject. In time the dreamy mysticism of astrology gave place to the wonderful science of astronomy.

Talismans are astrological charms or stones on which are engraven letters, figures or characters supposed to have great virtue in averting evil or disease. By ancient usage they were made when two planets came in conjunction. Sir Walter Scott in "The Talisman" tells of the "Lee-penny" which is still reputed to have virtue in stopping blood or canine madness.

Quite similar in form and use to the talismans were the amulets, except they were not fashioned under astrological influence. The image of Raphael (healer of God), patron angel of early Christians, was frequently found on both talismans and amulets. Images of the thing dreaded were sometimes placed upon amulets to frighten the real object of fear away. Frequently inscribed upon amulets were certain geometric figures or numbers. Among the Chaldeans the number seven was sacred, and according to their belief possessed a charm to ward off evil influences. The *crux ansota* was an Egyptian symbol of life, a cross worn suspended from the neck.

Amulet rings were held in high esteem in early times. The Signet of Solomon is said to have played a considerable part in the building of the temple. The Physician's Ring was an amulet prized both for its magical symbols as well as for its stone setting. Sapphire was reputed to shield the wearer from pestilence; coral was supposed to be curative for nervous and mental afflictions; and the opal was considered a stone of evil omen.

Of all amulets the Pentacle or five pointed star is the most ancient and honorable. It was called "Pentalpha" by Pythagoras, whose philosophy was that all knowledge and wisdom sprang from numbers. It constituted the legendary "Key of Solomon" which has entered so largely into history. Ruskin defined it as the Symbol of the Trinity. Long before the Wise Men of the East followed the lead of the Star of Bethlehem, the Pentacle was thought to have mysterious power. Like the horseshoe in our own day, it was employed to keep off witches, and bring good fortune. It was used as the heading of books written by the early Greek Christians. Goethe makes Dr. Faust place a Pentacle over his threshold to keep out the evil one, yet Mephisto got in. Among both ancient Greeks and Romans it was the symbol of health. Over each of the five arms of the star was placed the letter entering into the spelling of the word Hygeia (Greek) or Salus (Roman). This knowledge of the ancient meaning of the Pentacle, gives new significance to the stars on our national emblem.

In more recent times, it may be mentioned, amulets were issued in the form of "Touch Pieces" by Henry the VII to persons whom he had "touched" for the "Evil." In our own time the "Medicine Bag" of the American Indians is a familiar illustration of an amulet. It is made from the skin of a serpent or animal, and contains secret and mysterious substances, suggested by dreams inspired by the Great Spirit.

So much in brief is the medical symbolism which has come down to us from the far east, more particularly through Greek Mythology and the classical period of its civilization. Contrasting the highly mythical period of Aesculapius with the even more remarkable period of scientific inquiry inaugurated by Hippocrates, one is inclined to ponder what may have been the bearing of the latter toward the mysticism of the preceding ages. I am pleased to find abundant proof of his reverential attitude toward his predecessors. Sweeping as was his search for truth and keen his judgment of error, he yet had the modesty of a finer wisdom. Despite his vast knowledge and marvelous influence he did not arrogate to himself any subtle powers or seek to capitalize the mystical beliefs of the people for his own glory. On the contrary, note the humility of the truly great, when in the Hippocratic Oath he acknowledges a power greater than man and his indebtedness to those who had gone before. If in the Oath he lifts his thoughts toward Apollo the God of Medicine and pays tribute to the Aesculapians, it is not to be construed that he accepted unqualifiedly the medical myths of that period, but that he looked upon these medical symbols in an age of mysticism as an expression of the struggles of medicine to free itself from barbarism and superstition. With tender compassion he looked upon these beliefs and read into them the scientific hope of the future.

In this brief review of medical symbolism may we not have brought to attention one of the strongest attributes of Hippocrates—greatest physician of all time. If he, laboring in an ancient civilization which had been saturated with medical mysticism, was yet able to accomplish stupendous advancement in banishing superstition and establishing scientific truth, may we not learn from his methods and take courage from his action, in laying hold upon similar problems in the present age. And let us not with ostrich-like cowardice, hide our minds from the existence of superstition and mysticism in medical practice in modern civilization when in truth they are found upon every hand. The *nomen* (name) is different but the *numen* (the thing itself) is much like that of old. Marching under the same banner of mystic belief and practice as in the ancient days are Schlatterism, Dowieism, Eddyism, Chiropracticism and the like—a heterogeneous multitude of erratic, misguided, ignorant or venal-minded individuals. As Hippocrates spoke, not with the voice of cynicism, but in the spirit of charity, so let us not without just ground attack the votaries of isms and cults which feed upon medical mysticism. Nor should we allow pride to deter us from stooping to garner the grains of truth from the chaff of their errors.

On the other hand great injustice would be done the Father of Medicine in assuming that in his treatment of mystic beliefs and cults he shunted duty for expediency. Whilst his wonderful life was characterized chiefly by his zeal in the promulgation of scientific truth, and ethical conduct, he was equally determined in his opposition to sham. Let us not show less courage in the present generation. Never through our own neglect of duty in practice should these sects find justification for existence. Or when once established in the graces of public respect, we should not through a false conception of professional pride, disdain to lay bare by systematic and unrelenting exposure the loss of life which such practices often entail; or the golden opportunities wasted when sane and intelligent medical procedure might preserve or restore health. Altogether too soft has been our treatment of these fallacies. What respect have we for those cloaked in the garb of moral or religious creed who disdain to point to evil practices and fail to seek their reformation? Is not the medical profession perhaps in need of a spiritual awakening—a conversion which will inspire zeal and merciless exposure of medical shams as well as promote the cause of scientific truth?

USE OF DRUGS IN INFANCY AND CHILDHOOD

In order to establish a standardized list of drugs essential to the treatment of the diseases of infancy and childhood, Henry F. Helmholz, Rochester, Minnesóta (*Journal A. M. A.*, Oct. 8, 1921) selected from the pharmacopeia a list of sixty-one drugs. This list he sent to ieghty-four men who are limiting their practice to pediatrics, with the request that they check the drugs listed and add to them any drugs which they considered essential in their practice. Of the eighty-four men, sixty-four responded. Only mercury in some form and santonin, on the list submitted, are used by all sixty-four men. Besides these, silver, arsenic, iron, sodium bicarbonate, cod liver oil, and at least one representative of the opium series, the antispasmodics, heart and circulatory stimulants, hypnotics, laxatives, antipyretics, anthelmintics and urinary antiseptics, were used by sixty men of the sixty-four. One-half of the men used forty-three of the drugs indicated on the list. Fourteen added milk of magnesia, and three or more added benzyl benzoate, hyoscyamin, chloroform, agar-agar, creosote, chenopodium, glycerin, and tincture benzoin compound. One man added thirty-eight drugs to the list. The drugs in this list can be readily divided into four groups. The drugs in the first group have specific indications; for example, mercury, arsenic, quinine, santonin, male fern, and so forth, act directly in destroying parasites, and the drugs such as silver, hexamethylenamin and the salicylates, have definite antiseptic powers for destroying bacteria. The indication for the use of these drugs is usually given with the diagnosis of the disease. The drugs in the second group regulate the function of the different organs; for example, digitalis, the group of laxatives, and the diuretics. The third group is essentially for the symptomatic treatment of disease, as morphine for the relief of pain. The fourth group consists of drugs that are used for a specific purpose, and for practically no other, such as phosphorus in the treatment of rickets and spasmophilia, mustard for counterirritation, and phenol (carbolic acid) for the infections of the middle ear. The treatment by drugs of diseases in infancy is influenced in its effectiveness by the factor of nutrition and growth. This is perhaps best expressed by the statement that as long as a child eats and digests well there is a good chance for recovery. A drug which acts favorably on the disease focus but interferes with the nutrition of the child is harmful. The effect of the so-called tonic treatment during the active stage of the disease is another example of the failure to recognize the nutritional factor in disease.

EDITORIALS

A NEW SYNTHETIC LOCAL ANESTHETIC

A few weeks ago a new synthetic local anesthetic, the trade name of which is butyn, was placed on the market after having been approved by the Council on Pharmacy and Chemistry of the A. M. A. While most of us have been well satisfied with cocain as a topical application to produce local anesthesia, and procaine and apothesine for infiltration anesthesia, yet we are always pleased to find something that is either better or does away with some of the objections to these preparations. According to the report concerning clinical and experimental use, butyn is noted for the striking rapidity of its anesthetic action as also the depth and completeness of anesthesia produced in the average case, when used as a topical application for surface anesthesia. Generally speaking it is used just as cocain is used for surface anesthesia, namely, in two to five percent solutions, and in one-half percent solutions for infiltration anesthesia. On the conjunctiva it has one objectionable side action, and that is the production of a hyperemia, though this effect is controlled readily by the addition of epinephrin to the butyn solutions. It has the advantage of not dilating the pupil nor drying the cornea, as does cocain, and having no ischemic effect, it does not contract the tissues, as does cocain, thus making it especially desirable in nose and throat work. As far as toxic effects are concerned, that question will have to be decided by accumulated experience in the use of the preparation, and up to the present time clinical trial seems to indicate that it is no more and perhaps less toxic than cocain. Of decided value is the fact that butyn requires no narcotic blank and it is not thought that the drug is habit forming to the slightest extent.

With a growing tendency to do more and more surgery under local anesthesia, the value of procaine, apothesine and now butyn becomes of especial interest to all medical men, and we shall watch with interest the career of this new synthetic local anesthetic which bids fair to take a fixed place in our surgical work.

ANOTHER INFLUENZA EPIDEMIC

Several weeks ago reports were received showing that influenza was prevalent in many foreign countries and extending its sphere of action. Since then we have learned that the epidemic lasts from four to six weeks, that the type of the disease is much milder than in 1918, and broncho-pneumonia is the chief complication. A general spread of the infection is indicated from the fact that the disease has been following the main lines of travel and has finally developed in New York and is gradually spreading throughout the United States. It is now prevalent in several sections of Indiana, there having been reported a number of cases in Indianapolis and other cities. The character of the disease as it appears in this country is the same as that which has been prevalent in European countries, being mild in type, and broncho-pneumonia is the chief complication, but with a very noticeable lower percentage of deaths. There is, however, a tendency for the development of accessory sinus diseases and some neuroses which have a tendency to prolong the convalescence. Notwithstanding the fact that very much has been done in the way of experimenting as to the most efficient means of treatment, including extended trial with vaccines, but little has been accomplished in retarding the progress or limiting the ravages of the disease. Little or no protection against pneumonia has been afforded by the use of vaccines. Prevention seems to be of most importance. Attention to the recognized hygienic regulations is of more value than anything else. The reassuring feature of the present outbreak of the epidemic is that the disease is mild in character.

CAMOUFLAGED SALESMANSHIP

Have you ever heard stock salesmen say, "Our company has been passed by the State Securities Commission. Yes, sir, the State endorses this proposition and I guess if it is good enough to be endorsed by the State it is good enough for you!"? It is known that stock salesmen often have used as a talking point the fact that they are representing companies that have passed the Securities Commission to try to make their prospective buyers believe that the State endorses the stock they are selling.

Right here we want to impress this thought firmly in your mind—the State *does not* endorse any stock that is passed by the Securities Commission. In fact, it specifically says in the Blue Sky Law that one of the qualifications of advertising the fact that a stock is certificated is that there must also be a statement, printed in bold type, to the effect that " the Commissioner in no wise recommends such securities or other property".

So, when a salesman tries to impress you with the fact that his stock has been passed by the

Blue Sky Law, just remember this little part of the Blue Sky Law outlined in this story. It may save you money.

The Securities Commission examines properties for which stock is to be sold and makes certain restrictions as to how much stock shall be sold and on what basis. But it does not in any sense attempt to say that the proposition is a good one or a bad one.

The slogan, "Before You Invest—Investigate," still holds good. You are the one who is to decide how you are going to spend your money. Be wise and find out all about the proposition before you let somebody else use your earnings.

INCOME TAX RETURNS FOR 1921

The time is again at hand when physicians, along with all other individuals, must file their federal income tax returns for 1921. This report must be in the hands of the collector of internal revenue of your district before March 15, and must be accompanied by a remittance covering at least one-fourth of the tax for the year. Since last year several changes have been made in the law. The law at present requires that a return shall be made by the following individuals:

1. Every individual having a net income for the taxable year of $1,000 or over, if single, or if married and not living with husband or wife.

2. Every individual having a net income for the taxable year of $2,000 or over, if married and living with husband or wife; and,

3. Every individual having a gross income for the taxable year of $5,000 or over, regardless of the amount of his net income.

The normal and surtax rates for the year 1921 under the new law are the same as for the year 1920. However, the specific exemptions have been increased, except in the case of a single person, who is entitled to an exemption of only $1,000 as heretofore.

The head of a family, or a married person living with husband or wife, is allowed an exemption of $2,500, unless the net income is in excess of $5,000, in which case the allowable exemption is only $2,000. The old law allowed a flat exemption of $2,000 to the head of a family or a married person.

An exemption of $400 is allowed for each dependent under 18 years of age, or who is incapable of self-support because mentally or physically defective, instead of $200, as under the revenue act of 1918.

Practicing physicians are permitted to take into consideration the legitimate expense incident to their practice in addition to the exemptions for dependents and other general deductions. In view of the fact that some physicians failed to take advantage of some of these deductions last year, we are publishing detailed information herewith:

General Exemptions. If married, the physician may first record a deduction this year of $2,500, if his income is $5,000 or less, in place of $2,000 last year from his gross income. If single, he may deduct $1,000. For each child or dependent under the age of eighteen he is allowed a further deduction of $400, instead of $200, as last year.

Office Rentals. If the physician owns his own house and has his office in one room of that house, he may *not* claim a deduction for office rent. But if he pays rent to another person, for the use of the office space, he is permitted to deduct the amount expended for the rent of that office.

Automobile. Exemption may be claimed for the cost, repair and upkeep of automobile or other vehicle which is used exclusively in the conduct of a physician's business. The salary of the chauffeur, if most of his time is spent in driving to professional calls, may also be deducted. Amounts spent for the hire of taxicabs, and also street car fares, *on business calls,* may be taken off.

Assistants. Exemptions may be claimed for the salary of a nurse, laboratory assistant, stenographer, or clerical worker in the office, whose work is connected with the doctor's professional duties. Deduction also may be made for the salary of a maid or other person who spends her time in opening the door or answering the office telephone. Deductions may be made for that proportion of wages or salaries paid to employes in return for service directly in connection with practice or in connection with the care or treatment of patients.

Medicines, Instruments, Supplies. A doctor may take off an item for medicines used in the office in the treatment of patients. Bandaging, laboratory material, and all other supplies necessary to the running of a physician's office are permitted to be deducted.

On surgical instruments, he may charge off on an instrument with a fair average life of five years, one-fifth of its original cost each year.

General Office Expense. Telephone bills in their entirety may be deducted, because it is understood that the telephone in a doctor's office, even when that office is in his home, is almost entirely used for professional purposes.

Exemption is permitted for the correct proportion of expenditures made for light, heat and water. Depreciation of 10 percent of the original cost each year is allowed upon office furniture, it being considered that furniture should last about ten years.

Library. Most doctors have a medical library more or less extensive. In the courts it has been decided that after ten years a medical book is out of date and therefore worthless. For this reason the doctor is allowed a depreciation item of ten percent each year on his medical library.

Taxes, Licenses. Any taxes which a doctor may be required to pay upon materials which are required for his work may be deducted, and all licenses which he is by the nature of his business required to take out may be taken off of his gross income reported. This includes his license to prescribe alcohol, narcotic license, automobile tax, local occupational taxes and so forth.

Professional Dues. Also, a doctor may deduct dues paid to professional associations to which, in the interest of his business, he belongs, and exemption is also allowed for subscriptions to all medical newspapers and journals.

When to Deduct Unpaid Debts. If his books are kept according to the "Cash Receipts and Disbursements" system, he may not charge off any unpaid debts, because as explained in the tax manual, "if his books are kept according to this system, he is only reporting as gross income those accounts which have proved to be good, and therefore bad accounts cannot be deducted because they have already been excluded.

If the books be kept on an "Accrual" basis (that is, on the basis of expenses actually incurred and payable even though not yet paid, or income earned although not yet collected), it is permitted that the doctor may charge on his income tax blanks all debts which are definitely ascertained to be worthless during the year past.

In the same way, the doctor is permitted to claim deductions, for all other expenses within the scope of his profession, and the amount of his tax is determined on the net income which remains after all of these items have been deducted.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

THE JOURNAL office is in need of the January 15, 1921, issue of the *Journal of the A. M. A.* (Volume 76, No. 3) to complete the files for binding, and the A. M. A. office is unable to furnish same. Accordingly, if any reader has this copy which he does not care to retain for his own files, THE JOURNAL will appreciate the courtesy in sending it in to this office for the files here.

EVERY county medical society in the United States has received some resolutions calling for reforms in the A. M. A. and indicating that reforms can be accomplished only by change of leadership. Perhaps those who for many years have dictated the policies of the A. M. A. may see the "handwriting on the wall" and change their tactics, but we haven't much faith in reformation.

WE published in the January number of *The Journal* the obituary of Dr. Greenly V. Woollen, of Indianapolis, who died December 10. Dr. G. W. H. Kemper, for many years historian of the Indiana State Medical Association, calls our attention to an erroneous statement in the obituary which credits Dr. Woollen with being one of the founders of the Indiana State Medical Association. Inasmuch as this Association was founded in 1849, and Dr. Woollen was born in 1840, it is very evident that he had nothing to do with the founding of the Association, even though he was actively interested in it during some of the earlier years of its existence.

INDUSTRIAL Insurance Companies usually want a doctor to dress a wound for a dollar and then spend the rest of the month making out reports for them. They then kick on the bills, and they make it a rule to kick, no matter what the charges may be. The worst of the situation is that when some doctor has a controversy with an insurance company concerning a perfectly modest bill, a number of his confreres will come forward with the statement that the bill is excessive, notwithstanding the fact that, under similar circumstances, they themselves would try to collect satisfactory fees. Such is the cooperation and loyalty of certain men in the profession.

INDIANAPOLIS now boasts of some chiropractic colleges and, while Fort Wayne with its numerous chiropractic schools may have set the pace, it remains to be seen if the capital city does not eventually take the lead because of the fact that it is the capital of the state, centrally located, and, with its large population, offers a fertile field for the acquisition of students. It is possible that the State Board of Medical Registration and Examination may not relish the sight of chiropractic colleges right in the shadow of the capitol building, but there is no use in worrying about a little thing like that. We have been unable to enforce our medical practice acts, so why look with disfavor upon chiropractors or any other medical law breakers?

OUR editorial note in the January number concerning discrimination in the awarding of hotel reservations for the annual session of the A. M. A. has brought down upon our heads the wrath of the lordly secretary of the A. M. A. who seemingly disputes the right of anyone to question his acts. The subject under discussion is not settled by specious and misleading explanations nor by questioning the veracity of anyone who calls attention to the matter. Facts are stubborn things which are hard to down. To use an old saying, "It is a long lane that has no turn," and as we are accumulating some rather interesting information, we shall have something to say upon the subject later.

THE chiropractors are getting more nervy every day. In Ohio the "State Chiropractic Institute", located in Columbus, has been sending out to various physicians of Ohio invitations to take a "two weeks' course of instructions, *for physicians exclusively,* in the technic of chiropractic adjustments". The amusing feature of the announcement contains the information that this is a new field of scientific research for the medical profession. Evidently this is a new species of advertisement and it will redound to the profit of the chiropractors through the mistaken notion on the part of the public that chiropractic adjustments have a scientific basis and that the regular medical profession, in its long and honorable career, has been unable to discover the value of a method of treatment which has been nurtured in ignorance and quackery.

THAT there is profit in a well managed company furnishing medico-legal defense in malpractice suits is attested by the fact that the Medical Protective Company of Fort Wayne now has over one million dollars in assets. An enormous business has been built up by this company which makes a specialty of the medical defense business. In justice to the company it may be said that it never has defaulted to the slightest extent on a single contract ever issued, and all of the officers and directors of the company have established reputations for integrity. It is unfortunate that occasionally a suit for malpractice is brought against a physician, usually without justifiable cause, but it is fortunate that protection may be secured through insurance that guarantees appropriate attention to the interests of the physician who has been sued.

IN asking for increased patronage of the advertising section of the Journal of the Michigan State Medical Society, the editor calls attention to the fact that the expense of publication has increased over four hundred per cent. during the past five years, with little chance of any marked decrease in the cost for some time to come. The necessity for increased incomes in order to maintain or improve the present standard of medical periodicals is the excuse for asking the readers of state journals to increase advertising income by patronizing the advertisers whenever consistent to do so, and thus making the advertisers feel that they are receiving adequate returns for the money expended. What is true concerning the publication of the Michigan State Journal is true of the publication of every other state journal, but the difficulties may be met by the co-operation of everyone interested in the success of the state medical journals.

THE doctors who make up the rank and file of the medical profession should bear in mind one fact, and that is that not one of the various schemes to socialize medicine has developed in the minds of lay individuals. They are proposed and supported by erstwhile leaders in the medical profession. The public is not demanding any such schemes as "pay clinics" as inaugurated by Cornell University, or "community clinics" advocated by Hugh Cabot of the University of Michigan, or the fifty-seven varieties of free clinics for the well-to-do proposed by public health officers. The people in the United States, even the poorest, receive better medical and surgical attention than is given the people of any other country in the world. It is time to analyze the motives of the leaders in our profession when they propose radical innovations in the way of care for suffering humanity. Usually there will be found a "nigger in the wood pile" in the form of a desire for personal preferment or profit. However, "the worm is beginning to turn," and henceforth the uplifters in our profession will have to watch their steps!

IT IS unfortunate that the wording of an editorial note in the January number of *The Journal* gives occasion for doubt as to the character of the services being rendered by the chairman of the hotel committee for the St. Louis session of the A. M. A.

As a matter of fact the intention was to call attention to the large number of reservations made by the Secretary at the leading hotel where the annual session of the A. M. A. is held, with early subsequent announcement by the hotel that all available accommodations had been reserved, and that if one played in luck perhaps good reservations would be secured through the chairman of the hotel committee.

While the wording in the editorial note could be interpreted as a reflection upon the chairman of the hotel committee, yet no unfavorable meaning in that direction was intended. Sufficient evidence is at hand to indicate that there has been considerable jugglery in the assignment of hotel reservations for the annual sessions of the A. M. A. and it was with the idea of calling attention to an abuse of position or privilege, or both, that brought forth the editorial note to which attention is called, and which may have led to a misinterpretation of the meaning concerning the fairness of the chairman of the hotel committee for the St. Louis session who, so far as we know, is not engaged in the practice of which complaint is made.

QUITE a large number of county medical societies in Indiana have passed the resolutions sent out by a medical advisory committee of which Dr. McMechan, of Ohio, is secretary. Among the evils aimed at by the resolutions are:

(1) Foundation control of "full time" medical education.

(2) Lay board domination and the "closed shop" hospital.

(3) Socialized state medicine, subsidized community health centers and hospitals under political or university control.

(4) Legislative dictation of therapy and fees.

(5) Demoralization of medical standards by the expansion of cults.

(6) Exploitation of the specialties by lay technicians.

The resolutions call upon delegates to the A. M. A. to vote for a change of policy and leadership in the A. M. A. There are good reasons for the adoption of the resolutions, and there is every reason why the House of Delegates of the A. M. A. should carry out, in the main, the suggestions offered.

THE members of the Hendricks County (Indiana) Medical Society are opposed to treating people who patronize pseudo-medical cults and who are in the habit of calling regular physicians as a last resort or for the purpose of signing the death certificate. At the meeting, January 27, 1922, the Society passed the following resolutions:

"Whereas, certain pseudo-medical cults, including Christian Science practitioners, chiropractors, etc., are showing great activity with their propaganda, and

"Whereas, some people employ these pseudo-healers to treat dangerous diseases and continue treatment with said pseudo-healers until the disease becomes incurable or until the patient is almost dead and then a regular physician is called to take charge of the case in order that he may sign a death certificate; therefore, be it

"Resolved, That the members of the Hendricks County Medical Society refuse to attend patients who have treated with the pseudo-healers until in a hopeless condition or until nearly dead; and that members refuse to sign death certificates under such conditions; and be it further

"Resolved, That members refuse to treat patients who are at the same time taking treatment from the pseudo-healers."

INDIANA doctors may be interested in knowing that there is an organized ring conducting fake soliciting schemes, and that this ring owns a clearing house of information to aid in the collection of money. The ring maintains a list of possible prospects which is furnished to the individual members of the ring, together with such information concerning the nature of the prospect as seems necessary in order to effect a collection with him. Very naturally an attempt is made to make it appear that the object for which funds are solicited is a most deserving one and should be supported by business and professional men. The ring is able to furnish a subscription list containing signatures of heads of large business houses, manufacturers, and professional men, showing that these firms and individuals already have contributed, and the amount contributed. These lists usually are subscription lists of some scheme recently promoted, and from which all trace of the old plea has been removed. The ring is constantly exchanging ideas and suggestions, not only of lucrative districts but upon good schemes. Better Business Bureaus all over the country are warning merchants, professional men, and others against these fake soliciting schemes, and it is suggested to all those who are tempted to contribute to any cause, or to aid in any promotion scheme, that full information be obtained from the nearest Better Business Bureau before parting with any money, and in this way perhaps avoid being duped and defrauded by some smooth solicitor.

ACCORDING to the February number of the *Journal of the Michigan State Medical Society* the representatives of the Medical Department of the University of Michigan met with the

Council of the Michigan State Medical Society in Detroit early in January and discussed very freely the future activities and policy of the University as it pertains to medical issues and especially the new form of danger that threatens us—socialized medicine. From all we can learn there seems to be a desire to get together on a constructive policy, and the University authorities volunteered the information that they desired the good will and co-operation of the profession of Michigan. It was claimed by those in attendance at the conference that the University was not in favor of so-called State Medicine, and yet no explanation was made concerning the various moves on the part of the University, including the proposal to establish community clinics by the University, which certainly have a tendency to establish medical practice under state control, the one thing to which we are objecting strenuously. Furthermore, the report of the conference does not show that there was any explanation made concerning the reasons for building and equipping hospital facilities at Ann Arbor far beyond the purely teaching needs of the institution. If we are to have community clinics let us confine those clinics to the deserving poor, and let the compensation for the services be in keeping with the ability of the patients to pay, but above everything else we should have those clinics divorced from any kind of federal, state or municipal control with all of the evils attending such bureaucratic management.

IF we can judge by the discussion of the subject in medical societies and medical press it is very evident that the rank and file of the medical profession is awakening to the dangers that threaten the adoption of certain forms of socialized medicine as advocated by would-be reformers and philanthropists. It will be a sorry day for the people as well as the individual members of the medical profession when the practice of medicine is under the control of the State. The results of such a pernicious system are seen in some of the foreign countries where the majority of the people are given inefficient and indifferent care and the individual members of the medical profession are reduced to a position that is economically worse than that of the most ordinary craftsman. This idea of building county or state hospitals in every populous community and opening them to the public free of charge to any and all who may come, or the establishment of community clinics by our state universities or public health boards with the idea of furnishing gratuitous medical and surgical services to the people, sounds rather innocent when presented by some of the uplifters but it is a dangerous proposition. As a matter of fact the people are not suffering for want of skilled attention if they desire to have it, and all of these efforts to improve conditions are sponsored for the most part by members of our profession who are either misguided or have personal ends to gain. It is quite possible that there is a need for more and better medical and surgical attention for the masses, but why discuss plans which in the end will prove detrimental to the medical profession as well as the public? Why not systematize our efforts to give more and better service to the people by greater co-operation among medical men in the various communities.

OUR readers may remember that Cornell University announced a few months ago that it would open a pay clinic. Very naturally, this scheme opened competition with the medical profession. It was bound to result in opposition of the medical profession eventually. Now the Bronx County Medical Society, of New York, at a meeting held on November 16, 1921, unanimously adopted the following resolutions and recommendations:

"RESOLVED: That we protest against the abolition of the Poor Clinic by Cornell University and against the entrance of the University into commercial medicine for a profit.

"That the establishment of Pay Clinics by a University is inimical to the best interests of the public at large and of the medical profession in particular because such Clinics are in direct competition with the physicians who practice in the immediate and remote vicinity.

"That the offer of cooperation by the University with the general practitioner is a blind to beguile the latter to refer cases to them.

"That we condemn the conduct of the physicians who permitted their names and their positions to be used for such crass newspaper publicity as the advance announcements contained.

"That such advertisement is distinctly adverse to the best actions of Medical Men and to the Code of Ethics as established by the American Medical Association.

"That we recognize that these very men will not and cannot offer their services to the patient but will merely act in an advisory capacity far from the clinic rooms.

"That for all the above reasons we recommend that the respective County Societies to which these men belong and under whose jurisdiction Cornell University Medical School exists shall take proper and fitting action to reprimand these men and the University, and furthermore, shall recommend to its members that they not accept positions in a Dispensary that works to the economic detriment of their brethren."

IN evidence of the inconsistency of the average insurance company, we desire to call attention to some interesting correspondence that one of our councillors has engaged in, in an effort to establish the fact that a physician should receive compensation for services rendered an insurance company. In brief the facts are as follows: The insurance company wrote the doctor concerning one of his patients who had applied for insurance as follows: "Before issuing him further insurance we would like to know your opinion of the applicant's health condition, what possible effects you think his injury would have on any future illness, what resistance would he have, and what his health condition is at the present time." To this letter the doctor replied that he charged five dollars for such an opinion and that he would send it upon receipt of check covering the charges. The insurance company came back with the explanation that the answers desired were to secure further information concerning the applicant's physical condition so that proper decision could be made whether the risk was acceptable or not. As indicating how gullible medical men are the company said: "This is the first occasion in doing a nation-wide business that we have received a letter from a physician withholding the information desired until receiving a fee." A very appropriate answer came from the doctor and was as follows:

"I presume that you are in business to earn dividends upon your stock, and when you insure a member you charge him such rate of premium as the experience of your company and others has shown to be adequate to pay his average rate of loss and earn you something for your trouble. That is right and fair.

"I am practicing medicine to maintain myself and family and to accumulate some reserve against old age and disability. I have a fairly accurate knowledge of what it costs me to serve each patient who comes to my office and whom I may visit, and I know what charge is reasonable for the services rendered, and which I must make if I am to maintain myself. In practicing my profession I am selling my services and my knowledge of the human body and the cure of its ailments, and unless I receive money for this service I cannot support myself and my family, pay rents, office girl, drugs, telephone, new equipment, upkeep, etc.

"You write me as follows: 'We would like to know your opinion of the applicant's health condition, what possible effect you think his injury would have on any future illness, what resistance would he have, and what his health condition is at the present time.'

"You are asking me to render you an expert opinion of this applicant's health for the purpose of protecting you in your business, and this opinion you should be willing to pay for and you certainly will pay for it if you or any other insurance company obtain such a statement from me. The fee of five dollars asked of you is certainly a very small one for such a service. The fact that you have found the medical men as a class such easy marks that you can 'work' them and secure their services for nothing to protect you and your business is one of the outstanding facts that go to show the present spineless condition of the majority of my profession. I am pleased to know that I am a forerunner in this matter, and I feel sure that you will find more and more like me as time goes on.

"The applicant about whom you desire an opinion has received value in full for such fees as he has paid for any services I have rendered him, but if the answering of this inquiry were to protect him there might be some reason for me to grant him such courtesy; but I owe you nothing, and I am under no obligation to render you such gratuitous services to protect your company against loss."

To this letter the insurance company replied by "passing the buck" and placing the responsibility upon the applicant in furnishing information concerning physical condition. The company also has the nerve to say that all information concerning the physical condition of the applicant is of value to the applicant only, and that, accordingly, no provision is made for the payment of a medical examination or a medical opinion by the company. The average doctor "falls" for that kind of an argument, even though he knows that it is false. In reality the expert opinion concerning an insurance risk is of economic value to the company inasmuch as it undoubtedly is a means of saving the company from loss. It is a service that has a definite value on a basis of dollars and cents. The insurance company should pay for that service, and the only reason that it doesn't is because of the spineless attitude of the average medical man.

DEATHS

JOHN T. NEWTON, M.D., died at his home in St. Bernice, January 15, at the age of 73 years. Dr. Newton graduated from the Rush Medical College of Chicago in 1879.

EDWIN B. BRIGHAM, M.D., of Indianapolis, died at his home January 18 at the age of sixty-five years. Dr. Brigham was a graduate of the Indianapolis Physio-Medical College.

CYRUS L. WILSON, M.D., died January 18 at his home in Ewing, at the age of 68 years. Dr. Wilson graduated from the Medical Department of the University of Louisville in 1881.

CHARLES L. BOYD, M.D., of Paoli, died January 25 from the effects of paralysis, at the age of 68 years. Dr. Boyd graduated from the Medical College of Indiana, at Indianapolis, in 1881.

FREDERICK L. BUNCH, M.D., died January 10 at his home in Muncie, as a result of an illness caused by injuries received during the war. Dr. Bunch was 36 years of age and graduated from the Bennett Medical College in Chicago in 1907.

J. H. WARREN MEYER, M.D., died at Denver, Colorado, as the result of pneumonia, December 17, 1921, at the age of 38 years. Dr. Meyer was a lieutenant in the United States Navy, Recruiting Forces. He graduated from the Rush Medical College of Chicago in 1907.

SAMUEL C. LORING, M.D., died at his home in Plymouth, January 2, at the age of 62 years. Dr. Loring graduated from the Rush Medical College in Chicago in 1886 and was a member of the Marshall County Medical Society, the Indiana State Medical Association, the American Medical Association and the American College of Surgeons.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in *The Journal of the Indiana State Medical Association*. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

DR. A. E. RHYAN has been made county health officer of Parke County.

DR. CROUCH, of Fillmore, has been made county physician for Putnam County.

THE annual conference of health officers was held in Indianapolis, February 13 to 18.

VITAL statistics for 1921 show 67,850 births and 35,134 deaths in the State of Indiana.

THE Lawrence County Medical Society held its regular meeting January 4, 1922, at Bedford.

DR. HERMANN M. BIGGS has been re-elected president of the American Social Hygiene Association.

DR. E. M. CONRAD has been made health officer of Anderson, Indiana, to succeed Dr. J. A. Long.

THE office of Dr. E. H. Clauser at Muncie was entered Christmas night and a quantity of drugs stolen.

THE Public Health Nursing Association held a meeting in Indianapolis, January 12. Officers were elected.

FORTY-FIVE acres have been added to the gound area of the Sunnyside Sanitorium of Indianapolis.

DR. W. G. WEGNER, of South Bend, has opened new offices in the Farmers Trust Building of that city.

DR. S. G. WHITE, of Warsaw, was injured in an automobile accident, January 10. The injuries were not serious.

DR. and MRS. A. L. WILSON, of Indianapolis, were injured in an automobile accident January 3. Neither was seriously injured.

DRS. FITZPATRICK, COTTON and HOPPENRATH, of Elwood, have been made the new members of the city health board of that city.

THE Randolph County Medical Society held its regular meeting January 9. Dr. Hunt presented a paper on disease of the kidneys.

DR. JOHN A. PFAFF, of Indianapolis, has removed his office from the Bankers Trust Building to Suite 902-3 National City Bank Building.

THE office of Dr. B. F. Dudding, of Hope, Indiana, was broken into and robbed, December 30, of a large amount of opium and morphine.

THE Lake County Medical Society held a meeting January 12 at Gary. Papers were presented by Drs. Ira Miltimore and H. C. Parker.

DR. C. D. LANE, of Ligonier, is remodeling his office. The new office will include an operating room, x-ray room and two detention rooms.

DR. C. F. HOPE has moved from Coatsville to Shoals, Indiana, where he will practice medicine in the office formerly occupied by Dr. H. W. Shirley.

DR. HARRY L. FOREMAN, of Indianapolis, has announced his removal to new offices at 3005 North Illinois Street for the practice of general medicine and obstetrics.

THE Elkhart County Medical Society held a meeting at Goshen, January 5. A paper was presented by Dr. Albert J. Ochsner, of Chicago, on "Osteomyelitis".

THE Muncie Academy of Medicine held a meeting January 20 at the Hotel Roberts. A paper on "Epidemic Jaundice" was presented by Dr. S. C. Waters.

ACCORDING to an announcement made by the Children's Bureau, twenty-two states have accepted the provisions of the Sheppard-Towner Infant and Maternity Law.

THE Wabash County Medical Society held its regular monthly meeting at Wabash, January 20. Papers were presented by Drs. Fred Whistler and L. O. Sholty.

A HOME for nurses in the employ of the Schneck Memorial Hospital at Seymour, Indiana, has been presented by Mrs. Louise Schneck as a memorial to her husband.

THE Putnam County Medical Society held a meeting January 5 and the following officers were elected: Dr. R. H. Richards, president; Dr. C. C. Tucker, secretary-treasurer.

A NEW government hospital will be formally opened at Dawson Springs, Ky., February 22, according to an announcement made by Assistant Secretary of the Treasury Clifford.

THE Physicians' Club met at the St. Joseph's Hospital, Mishawaka, January 18. Dr. A. C. Yoder, of Goshen, presented a paper on "The Present Status of Chronic Gastritis".

DRS. E. E. HODGIN, W. H. FOREMAN, GOETHE LINK and ARTHUR E. GUEDEL have been made members of the new board of health of Indianapolis, recently appointed by Mayor Shank.

DR. D. F. CAMERON has been appointed assistant physician and surgeon for the Pennsylvania Railroad and has established offices in the Medical Arts Building in Fort Wayne.

THE Wells County Medical Society held its first meeting of the year at Bluffton, January 17. Dr. D. D. Jones, of Berne, presented a paper on "The Sympathetic Nervous System".

THE Delaware-Blackford Academy of Medicine held its first meeting of the year at Muncie, January 6. Dr. Robert Prebel addressed the meeting, his subject being "The Logic of Medicine."

THE *Red Cross Courier* will be a new weekly periodical published by the American Red Cross Society which will take the place of all bulletins now published at National and division headquarters.

THE Johnson County Medical Society has elected the following officers for 1922: Dr. J. A. Craig, president; Dr. Luke P. V. Williams, vice-president; Dr. A. T. Records, secretary-treasurer.

PLANS are being made for the erection of a million dollar office building for physicians in Indianapolis. The plans include a small hospital and operating room. The building is to be fifteen stories.

DRS. EDWARD KRUSE and LYMAN RAWLES, of Fort Wayne, have been appointed examining physicians for crippled children seeking treatment at the Shrine hospital now under construction at St. Louis.

PLANS were made for the opening of an office for the county health doctor and nurses, and the formulation of county health plans for this year were discussed for Marion County at a conference held January 5, 1922.

DR. JOSEPH MACDONALD, JR., editor and publisher of the *American Journal of Surgery* and co-publisher of *Medical Pickwick,* died suddenly in his office on January 7 of cerebral hemorrhage at the age of 51 years.

THE monthly meeting of the Clark County Medical Society was held January 3, 1922, and the following officers were elected: Dr. T. J. Marshall, president; Dr. A. H. Mead, vice-president; Dr. Giles E. Mowrer, secretary.

PLANS have been made for the establishment of a hospital for incurable patients who are now in the City Hospital at Indianapolis. More room is needed in the City Hospital for patients who can be restored to normal health.

THE Sullivan County Medical Society held a meeting January 20, 1922, and the following officers were elected: Dr. Paul Higbee, president; Dr. J. R. Crowder, vice-president; Dr. J. S. Brown, secretary-treasurer.

THE Treasury Department has approved the plans for the remodeling of the Bronx Hospital for the treatment of ex-service men. The hospital is to be ready for occupancy by March 15, and will be for the treatment of general cases.

AMERICAN Legion posts of Minnesota will erect a two hundred thousand dollar hospital where Drs. William and Charles Mayo will treat former soldiers of the world war. Patients will be charged according to their ability to pay.

DR. HOWARD B. CROSS, of the Rockefeller Institute of Medical Research, who went to Vera Cruz, Mexico, to study yellow fever, contracted the disease while inspecting sanitary conditions at Tuxtepec, and died at Vera Cruz, December 27.

DR. G. H. ESPINLAUB, of Indianapolis, and a nurse, Miss Villa Corzine, were injured in an automobile accident, January 13, when the ambulance in which they were making an emergency call was struck by a cattle truck. Neither was seriously injured.

THE Boone County Medical Society held its annual meeting Tuesday, January 3, at Lebanon and the following officers were elected: Dr. J. H. Black, president; Dr. John D. Coons, vice-president; Dr. E. H. Hare, secretary-treasurer; Dr. P. B. Little, delegate.

DURING January the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: The Abbott Laboratories, Butyn. G. W. Carnrick Co., Solution Post-Pituitary. Parke, Davis & Co., Pituitrin "O".

THE LaPorte County Medical Society held a meeting January 13, 1922, at Michigan City. A paper was presented by Dr. H. H. Martin on "Review of Gall Bladder and Gall Duct Therapy." The paper was discussed by Drs. E. G. Blinks, N. E. Funk, and J. V. Kerrigan.

DR. B. G. DUPRE has resigned his position of surgical assistant to Dr. H. A. Duemling of the Lutheran Hospital, Fort Wayne, to become surgical man at the Hope-Methodist Hospital of that city. Dr. H. L. Norris will fill the vacancy made by the resignation of Dr. Dupre.

AT a recent meeting of the Board of Regents of the University of Michigan it was voted to merge the homeopathic medical school with the medical school of the University. Last year there were but seven graduates from the homeopathic school and the cost of maintenance was more than $47,000.

WILLIAM C. VANARSDEL, 72 years old, died at his home in Indianapolis, January 8. Mr. VanArsdel was president of the board of trustees of the Methodist Hospital in Indianapolis until prevented from active participation in its affairs when he was made president emeritus of that institution for life.

DIVISIONS of child and infant hygiene and nursing of the State Board of Health were merged into one division at a meeting held in Indianapolis, January 11. The divisions were combined in order to meet the requirements of a Federal law so that an appropriation of $10,000 for the health work may be obtained.

THE Bartholomew County Medical Society held its annual meeting January 10 at Columbus where the following officers were elected: Dr. F. D. Norton, president; Dr. C. M. Jackson, vice-president; Dr. Lyman Overshiner, secretary-treasurer; Dr. George T. MacCoy, delegate, and Dr. O. A. Delong, alternate.

AT a meeting of the state board of medical registration and examination held at Indianapolis, January 12, the following officers were elected: Dr. W. A. Spurgeon, Muncie, president; Dr. E. M. Shanklin, Hammond, vice-president; Dr. W. T. Gott, Crawfordsville, secretary; Dr. Paul Tindall, Shelbyville, treasurer.

AT the Indianapolis session of the Indiana Academy of Ophthalmology and Otolaryngology, January 20, the following officers were elected: Dr. D. O. Kearby, president; Dr. H. C. Knapp, first vice-president; Dr. J. W. Carmack, second vice-president; Dr. B. W. Egan and Dr. M. Ravdin, counselors

FULTON, Delaware and Gibson counties have accepted the proposal of the international health board of the Rockefeller Foundation to provide a public health officer with specialized training for full time service in the county. It is desired to show the superiority of a full-time, specially trained man over the present system in use in this state.

AT a meeting of the Public Health Nursing Association held in Indianapolis, January 12, a resolution was made and passed to set aside $1,200.00 as a foundation fund to be used for carrying on the association work. It is to be known as the Addie Hunt Bryce fund, Mrs. Bryce having been one of the founders of the association.

DRS. GEORGE E. DE SCHWEINITZ, CHARLES W. RICHARDSON, and FRED B. LUND have been appointed as a committee on the Gorgas Memorial. This appointment was made to comply with a request from the Gorgas Memorial Institute of Tropical and Preventive Medicine of Panama for the cooperation of the American Medical Association.

AN independent appropriation bill presented to the lower house of Congress includes administrative expenses of the U. S. Veterans' Bureau. The measure carries $64,658,680 for medical and hospital service. This is an increase of $6,658,680 over the current fiscal year and is in accordance with the recommendation of the budget bureau.

DR. WALTER P. BOWERS has resigned as secretary of the Massachusetts Board of Registration in Medicine which position he has held since 1913, to assume the editorship of the *Boston Medical and Surgical Journal*. This Journal recently has been taken over by the Massachusetts Medical Society and under Dr. Bowers' editorship is undergoing a number of improvements.

COMPETITION is now open to non-members of the American Laryngological Association for the de Roaldes Prize. The prize is a gold medal valued at one hundred fifty dollars and will be presented for the best original thesis on a subject pertaining to laryngology or rhinology. Theses must be in the hands of the chairman of the prize committee, Dr. D. Bryson Delavan, 40 East Forty-first Street before the first of April.

A BILL for the reorganization of the United States Public Health Service has been introduced in the Congress. This bill provides that officers of the reserve corps of the Public Health Service, not to exceed 550, may be transferred to and commissioned in the regular corps of the service. The office of Surgeon General shall

be filled by appointment by the President for a term of four years. It also provides that there shall be a corps of nurses, dietitians, and reconstruction aides in the United States Public Health Service.

ACCORDING to an announcement, $1,320,000 has been appropriated for the erection of a new medical building at Yale University to be known as the Sterling Hall of Medicine. The building will contain a medical library of approximately twelve thousand volumes, an amphitheater with seating capacity of two hundred fifty, administrative offices of the dean and registrar, faculty room, students' common room, and single rooms for unmarried instructors in the preclinical subjects. A wing will provide laboratories on the first and second floors.

THE Adjutant-General has submitted a proposed legislation to Congress which establishes a definite law covering promotions in the Medical Corps of the Army. This legislation provides that an officer in the Medical Corps shall be promoted to the grade of captain after three years' service, to that of major after twelve years' service, to lieutenant-colonel after twenty years' service, and to the grade of colonel after twenty-six years' service. The purpose in this legislation is to increase the efficiency of the medical department of the Army.

ROBERT BURDINE, leper, who was discovered in Indianapolis, with anesthetic leprosy about two years ago, was placed under quarantine by the State Board of Health and treated with ethyl ester of Chaulmoogra oil. The Board has now pronounced him cured and discharged the quarantine. The most careful search does not find in the nose or elsewhere the lepra bacillus which at the beginning of the treatment was easily discovered, every slide showing the organism. The State Board of Health is compelled to assume that this leper is cured because there is no evidence that he has the disease and the law therefore cannot hold him.

THE United States Civil Service Commission announces that there is urgent need for reconstruction assistants and aides in physiotherapy and occupational therapy, trained nurses and physicians, to serve in hospitals and other establishments of the United States Public Health Service. Applications for these positions will be received by the Commission until further notice. Applicants will be rated upon their education, training, experience, and physical ability. Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the Secretary of the Local Board of Civil Service Examiners at the postoffice or customs house in any city.

THE U. S. Public Health Service announces a Venereal Disease Institute to be held under the direction of the Illinois State Department of Public Health at the Congress Hotel in Chicago, March 13-18, inclusive. Courses in syphilis, gonorrhea, the problem of prostitution and delinquency, clinics and their management, clinic social work and methods of health education will be given. Special features will include daily noon-day luncheons and evening clinics.

An invitation is extended to all physicians and especially those who are particularly interested in venereal diseases. Those who plan to attend are urged to register at once. Registration cards and programs may be obtained upon request from Dr. I. D. Rawlings, Director of Public Health, Springfield, Illinois.

A COURSE on Current Problems of Biochemistry and Experimental Medicine is offered by the Indiana University School of Medicine, the first lecture being delivered Wednesday, February 15, 1922, at 8:00 P. M. The course is conducted by Professor B. B. Turner and consists of eight lectures to be given on alternate Wednesday evenings at the Indiana University School of Medicine, Indianapolis. The second lecture will be given Wednesday, March 1, at 8:00 P. M.

The subjects discussed will include nutrition, intermediate metabolism of food substances, vitamines, basal metabolism, endocrine glands, kidney function and nephritis, acidosis, relation of chemical constitution to physiological action. The fee for the course will be $5.00.

For further particulars address Registrar, Indiana University School of Medicine, Indianapolis, Indiana.

One of the most important developments in the medical history of the past five years has been the work of the Council on Pharmacy and Chemistry, of the American Medical Association. Their examination and analysis of newer remedies has done much to advance the standard of manufacturing pharmacy; it is safeguarding the doctor against inferior products, and indicating those for which misleading claims are made.

The cooperation of the doctor in using and prescribing Council-Passed products is making this work more effective each year. The cooperation of the manufacturers is, also, an encouraging recognition of the value of this service. A partial list of the Council-Passed Remedies, manufactured by The Abbott Laboratories, Chicago, appears in this issue. These are obtainable on prescription at the leading pharmacies, or may be obtained direct, as desired.

THE COUNCIL

The regular mid-winter meeting of the Council of the Indiana State Medical Association was held in the Assembly Room at the Board of Trade Building, Indianapolis, Tuesday, January 10, 1922.

At 12.30 p. m. the Councilors were guests of President Davidson at luncheon after which the meeting convened with the following present: Drs. W. R. Davidson, E. M. Shanklin, E. M. Conrad, Joseph Schmadel, C. S. Black, J. H. Weinstein, E. E. Morgan, F. J. Spilman, Walter Leach, S. E. Earp, A. G. Osterman, W. R. Moffitt, and C. N. Combs.

The Chairman, Dr. Shanklin, presided. The minutes of the previous meeting were read and approved.

Dr. E. M. Shanklin was re-elected as Chairman of the Council for the year 1922.

Dr. A. E. Bulson, Jr., Editor of THE JOURNAL, was absent and no report was made.

The Councilors made their respective district reports. The Fourth District has had the best year of its existence. The Eleventh District at its district meeting voted to ask the Council to recommend changing Howard County from the Ninth District to the Eleventh District.

Dr. Black moved that the Council endorse the transfer of Howard County from the Ninth to the Eleventh District, and refer the proposal to the House of Delegates for final action.

Seconded by Dr. Moffitt.

Motion carried.

The Twelfth District Councilor has been furnishing programs for the weaker county societies, and finds that this plan is of great assistance to them. He recommends it to other district councilors.

The Council went into executive session and considered the case of Dr. J. Sater Nixon, Kokomo, versus the Howard County Medical Society. The Council unanimously voted to sustain the action of the Howard County Medical Society in expelling Dr. Nixon.

Adjourned.

CHARLES N. COMBS, Secretary.

SECRETARY'S REPORT

TO THE COUNCIL:

One year ago I ventured the prediction that we would be able to increase our membership in 1921, and it is now very gratifying to be able to report that such is the case.

Membership Jan. 1, 1921		2513
Died	28	
Left State, retired, etc	31	
Delinquent	114	173
		2340
New members		268
Membership Jan. 1, 1922		2608

In the past years, I have endeavored to stimulate rivalry between the county secretaries for the purpose of increasing the membership. This year I am taking the territory of the different councilors, and will publish the 1921 membership from each councilor district. Each month in THE JOURNAL, there will be published the 1922 membership to date for each of these districts with a percentage column for the purpose of comparison. Each councilor will be expected to be responsible for the membership of every eligible physician in his territory, and should have at the end of the year not less than a 100% enrollment.

Respectfully submitted,
CHARLES N. COMBS, Secretary.

TREASURER'S REPORT FOR THE YEAR 1921

GENERAL FUND

Balance on hand January 1, 1921		$ 7,028.40
Membership dues at $4.00 per member (2608 members)		10,428.00

CHARLES N. COMBS, Treasurer.

THE TRUTH ABOUT MEDICINES

PROPAGANDA FOR REFORM

NUFORAL.—This is a preparation advocated for the treatment of tuberculosis by the Nuforal Laboratories, New York. From the available evidence it appears evident that the use of Nuforal as a treatment for tuberculosis is a commercial proposition, and that the treatment is distinctly in the experimental stage. —(*Jour. A. M. A.*, Jan. 7, 1922, p. 59).

HELIOTHERAPY AND RICKETS.—Evidence for the value of heliotherapy in rickets was presented years ago. This value has recently been verified by experiments on animals rendered demonstrably rachitic through dietary errors. When rats have an abundance of sunlight, they remain healthy under regimens which are sufficiently deficient in phosphorus to induce rickets in animals kept in subdued light. It has been shown that the changes produced by

sunlight on the skeleton do not differ in any important respect from the changes produced when animals are fed cod liver oil. Again, sun treatment of infants suffering from rickets not only brings about a cure of the rachitic lesions, but in so doing occasions chemical changes in the blood similar to those noted when the cure is effected by cod liver oil. Heliotherapy has thus in one case at least been put upon the scientific basis of demonstrable chemical changes in the organism affected.—(*Jour. A. M. A.*, Jan. 21, 1922, p. 195).

WESTERN MEDICAL ASSOCIATION TREATMENT FOR EPILEPSY.—The Western Medical Association, Chicago, is selling a mail-order treatment for the alleged cure of epilepsy. The A. M. A. Chemical Laboratory examined the "Treatment" and found the essential constituent to be phenobarbital (luminal). The Laboratory reports that the "Treatment" is sold in three boxes, A. B. and C. "A" contained tablets, each of which represented 0.66 gm. (1 grain) of phenobarbital (luminal). "B" contained tablets which are of the type sold by pharmaceutical houses as "digestive tablets" and contained pepsin, pancreatin and calcium lactophosphate. "C" contained tablets which gave tests for emodin-bearing drugs and for aloin. In addition to the epilepsy treatment, the Western Medical Association also sells a number of other nostrums for the treatment of various diseases. Apparently, two men are mainly concerned in operating the Western Medical Association, namely, Joseph B. Creevy and Dr. W. W. Lister, a physician.—(*Jour. A. M. A.*, Jan. 28, 1922, p. 296).

ANTIDOTE FOR PHENOL POISONING.—Sodium sulphate in strong solution is one of the best known antidotes for phenol poisoning. The action is not a chemical one. Alcohol is not an antidote for phenol poisoning. Experiments carried out in the U. S. Hygienic Laboratory showed that the toxicity of phenol was increased by alcohol. Alcohol is applied to the appendix stump after operation in the belief that it will neutralize the action of the phenol and thus prevent extensive sloughing of the tissues; but no doubt the action of the alcohol is simply that of diluting and washing away the phenol.—(*Jour. A. M. A.*, Jan. 28, 1922, p. 299).

PINUSEPTOL.—According to the catalog of Eli Lilly & Company, Pinuseptol is a "Pine Oil Disinfectant". The Bureau of Chemistry of the U. S. Department of Agriculture has investigated the general subject of the use of pine oil as a disinfectant. It reports that emulsions made from pine oil when freshly prepared give a Hygienic Laboratory phenol coefficient of from 3.42 to 4.34. It was found that pine oil emulsions failed to kill M. aureus and B. anthracis; and the government chemists conclude that these products should not be used for general disinfecting purposes.—(*Jour. A. M. A.*, Jan. 28, 1922, p. 299).

NEW AND NONOFFICIAL REMEDIES

LIQUID PETROLATUM-SQUIBB, HEAVY (CALIFORNIA).—A brand of liquid petrolatum-U. S. P., made from California petroleum and claimed to be composed essentially of hydrocarbons of the naphthene series. For a description of liquid petrolatum, see the U. S. Pharmacopeia and Useful Drugs. E. R. Squibb & Sons, New York.

CHAULMOOGRA DERIVATIVES.—Chaulmoogra oil is a fixed (fatty) oil. In addition to small quantities of the glycerides commonly found in fats, chaulmoogra oil contains the glycerides of a series of highly unsaturated fatty acids, chiefly chaulmoogric acid and hydrocarpic acid. The therapeutic properties of chaulmoogra oil appear to be due to these unsaturated fatty acids. Chaulmoogra oil is used in the treatment of leprosy, the bulk of the evidence indicating that it is of value though it does not have specific curative properties. Chaulmoogra oil is given by mouth or hypodermic injection. The sodium salts of the fatty acids of chaulmoogra oil and the ethyl esters prepared from these fatty acids have been used in the treatment of leprosy with claims that they are better tolerated than the oil.

CHAULMOOGRA OIL.—OLEUM CHAULMOOGRAE.—For actions and uses, see the preceding article, "Chaulmoogra Derivatives". The dose is 0.3 Cc. (5 drops) in capsules, three times daily, the dose being increased to the point of tolerance. For hypodermic injection it has been used mixed with olive oil.

CHAULMESTROL.—Ethyl esters of the fatty acids of chaulmoogra oil. For a discussion of the actions and uses, see the preceding article, "Chaulmoogra Derivatives". Orally, chaulmestrol is administered in gradually increasing doses of from 1 Cc. to 5 Cc. Intramuscularly, 1 Cc. is the initial dose. The Bayer Company, New York (Winthrop Chemical Company, Inc., New York, distributor).—(*Jour. A. M. A.*, Jan. 14, 1922, p. 111).

FOOD ALLERGENS-SQUIBB.—Powders representing the protein of foods. For action, uses and dosage, see general article, "Biologically Reactive Food Proteins", New and Nonofficial Remedies, 1921, p. 65. The following allergens have been accepted: Almond Allergen-Squibb, Barley Allergen-Squibb, Brazil-Nut Allergen-Squibb, Buckwheat Allergen-Squibb, Butternut Allergen-Squibb, Chestnut Allergen-Squibb, Corn Allergen-Squibb, Filbert Allergen-Squibb, Hazelnut Allergen-Squibb, Hickory-Nut Allergen-Squibb, Oat Allergen-Squibb, Peanut Allergen-Squibb, Pecan Allergen-Squibb, Rice Allergen-Squibb, Rye Allergen-Squibb, Walnut (Black) Allergen-Squibb, Walnut (English) Allergen-Squibb, Wheat Allergen-Squibb, Apple Allergen-Squibb, Artichoke Allergen-Squibb, Asparagus Allergen-Squibb, Banana Allergen-Squibb, Blackberry Allergen-Squibb, Black Pepper Allergen-Squibb, Bean (Lima) Allergen-Squibb, Bean (Navy) Allergen-Squibb, Bean (String) Allergen-Squibb, Beet Allergen-Squibb, Cabbage Allergen-Squibb, Cantaloupe Allergen-Squibb, Carrot Allergen-Squibb, Celery Allergen-Squibb, Cherry Allergen-Squibb, Coffee Allergen-Squibb, Cucumber Allergen-Squibb, Eggplant Allergen-Squibb, Grape Allergen-Squibb, Grapefruit Allergen-Squibb, Lettuce Allergen-Squibb, Mustard Allergen-Squibb, Onion Allergen-Squibb, Orange Allergen-Squibb, Parsnip Allergen-Squibb, Pea Allergen-Squibb, Peach Allergen-Squibb, Pear Allergen-Squibb, Plum Allergen-Squibb, Potato (Sweet) Allergen-Squibb, Potato (White) Allergen-Squibb, Prune Allergen-Squibb, Radish Allergen-Squibb, Raspberry Allergen-Squibb, Rhubarb Allergen-Squibb, Spinach Allergen-Squibb, Squash Allergen-Squibb, Strawberry Allergen-Squibb, Tomato Allergen-Squibb, Turnip Allergen-Squibb, Watermelon Allergen-Squibb, Beef Allergen-Squibb, Bluefish Allergen-Squibb, Chicken Allergen-Squibb, Clam Allergen-Squibb, Codfish Allergen-Squibb, Crab Allergen-Squibb, Goose Allergen-Squibb, Haddock Allergen-Squibb, Halibut Allergen-Squibb, Horse Allergen-Squibb, Lamb Allergen-Squibb, Lobster Allergen-Squibb, Mackerel Allergen-Squibb, Mutton Allergen-Squibb, Oyster Allergen-Squibb, Pork Allergen-Squibb, Salmon Allergen-Squibb, Shrimp Allergen-Squibb, Sweetbreads Allergen-Squibb, Turkey Allergen-Squibb, Veal Allergen-Squibb, Milk (Cow) (All Proteins) Allergen-Squibb, Milk (Goat) (All Proteins) Allergen-Squibb, Milk (Human) (All Proteins) Allergen-Squibb, Milk (Cow) (Casein) Allergen-Squibb, Milk (Cow) (Albumin) Allergen-Squibb, Egg (White) (All Proteins) Allergen-Squibb, Egg (Yolk) (All Proteins) Allergen-Squibb, Egg White Albumin Allergen-Squibb, Egg (Whole) (All Proteins) Allergen-Squibb, Wheat

A Bloodless Field

is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 **Suprarenalin Solution** slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work **Pituitary Liquid** (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's Sterile Catgut Ligatures are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

HUNDREDS OF DOCTORS FIND WE SAVE THEM FROM 10% TO 25% ON X-RAY LABORATORY COSTS

AMONG THE MANY ARTICLES SOLD ARE

X-RAY PLATES. Three brands in stock for quick shipment. PARAGON Brand, for finest work; UNIVERSEAL Brand, where price is important.

X-RAY FILMS. Duplitized or Double Coated—all standard sizes. X-Ograph (metal backed) dental films at new, low prices Eastman films, fast or slow emulsion.

BARIUM SULPHATE. For stomach work. Finest grade. Low price.

COOLIDGE X-RAY TUBES. 5 Styles. 10 or 30 milliamp.—Radiator (small bulb), or broad, medium or fine focus, large bulb. Lead Glass Shields for Radiator type.

DEVELOPING TANKS. 4 or 8 compartments stone, will end your dark room troubles. 5 sizes of Enameled Steel Tanks.

DENTAL FILM MOUNTS. Black or gray cardboard with celluloid window or all celluloid type, one to eleven film openings. Special list and samples on request. Price includes your name and address.

DEVELOPER CHEMICALS. Metal, Hydroquinone, Hypo, etc.

INTENSIFYING SCREENS. Patterson, TE, or celluloid-backed screens. Reduce exposure to one-fourth or less. Double screens for film. All-metal Cassettes.

LEADED GLOVES AND APRONS. (New type glove, lower priced.)

FILING ENVELOPES with printed X-Ray form. (For used plates.) Order direct or through your dealer.

(Gliadin) Allergen-Squibb, Orris Root Allergen-Squibb. E. R. Squibb & Sons, New York.—(*Jour. A. M. A.*, Jan. 21, 1922, p. 192).

POLLEN PROTEIN ALLERGENS-SQUIBB.—Powders consisting of the sodium chloride-soluble protein of the isolated pollen from various species of plants. The Pollen Protein Allergens-Squibb are intended only for diagnosis. For action, uses and dosage, see general article, "Pollen Extract Preparations", New and Nonofficial Remedies 1921, page 239. The following allergens have been accepted: Corn Pollen Allergen-Squibb, Goldenrod Pollen Allergen-Squibb, Orchard Grass Pollen Allergen-Squibb, Ragweed Pollen Allergen-Squibb, Rye Pollen Allergen-Squibb, Timothy Pollen Allergen-Squibb. E. R. Squibb & Sons, New York.—(*Jour. A. M. A.*, Jan. 21, 1922, p. 193).

NEOCINCHOPHEN-ABBOTT.—A brand of neocinchophen-N. N. R. For action, uses and dosage, see New and Nonofficial Remedies 1921, p. 86. The Abbott Laboratories, Chicago.—(*Jour. A. M. A.*, Jan. 21, 1922, p. 192).

BOOK REVIEWS

ARTERIOSCLEROSIS AND HYPERTENSION WITH CHAPTERS ON BLOOD PRESSURE. By Louis M. Warfield, A.B., M.D. (Johns Hopkins), F.A.C.P.; formerly Professor of Clinical Medicine, Marquette University Medical School; Chief Physician to Milwaukee County Hospital; Associate Member Association American Physicians; Member American Association Pathologists and Bacteriologists; American Medical Association, etc., Fellow American College of Surgeons. Third Edition. Cloth, pp. 265. Price $4.00. Published by C. V. Mosby Company, St. Louis.

For a condensed volume on this important subject, it would be difficult indeed to find a more satisfactory digest of facts than obtains in this new edition of Dr Warfield's admirable book. Arteriosclerosis is here considered not so much as a disease with a definite etiologic factor as it is a degenerative process affecting the vascular system, following a variety of causes, the most characteristic causal factor being lues.

Much has been added to the chapter on blood pressure and the section on cardiac irregularities is both new and satisfying.

The subject of treatment alone is sufficiently comprehensive, yet withal terse, that it alone should win a place for the volume in the library of anyone interested in the subject of cardio-vascular diseases.

EPHRAIM MCDOWELL—"FATHER OF OVARIOTOMY" AND FOUNDER OF ABDOMINAL SURGERY—with an appendix on JANE TODD CRAWFORD. By August Schachner, M.D., F.A.C.S., Louisville, Kentucky. Octavo volume of about 350 pages. Attractively printed and profusely illustrated with plates in double tone. Price $5.00. J. B. Lippincott Company, Publishers. Philadelphia and London.

The author has given us an excellent history of the life and work of Ephraim McDowell. He has also given us the first history of Jane Todd Crawford —the woman who made McDowell's first ovariotomy a possibility.

McDowell's life story has been too long neglected and it behooves every American surgeon to read this book by Schachner. We can justly claim that McDowell is, in a sense, the Father of Abdominal Surgery. As the author states he "emphasized the possibility of invading the peritoneal cavity" and thus "he laid the cornerstone for the most brilliant domain of surgery".

Schachner maintains that had McDowell lived under the shadow of a great university he would never have been the first ovariotomist. "It was McDowell's frontier location on the very fringe of civilization, where freedom and self reliance reigned supreme, that made the first ovariotomy possible."

The Reviewer was rather saddened to learn that the generally accepted story, that an angry mob surrounded the house and threatened McDowell's life while he performed his first operation, is purely a myth. Of course, at the time of the operation, there was considerable excitement in the village of Danville and "a preacher from the pulpit called attention to the fact that Dr. McDowell was attempting an impossible thing, and in the event of the woman's death he would be a murderer".

Good taste and modesty should have dictated the exclusion of the foot-note on page 39 wherein the author, by indirection, compares himself to John Bell of Edinburgh.

ESSAYS ON SURGICAL SUBJECTS. By Sir Berkeley Moynihan, K.C.M.G., C.B., Leeds, England. Octavo of 253 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $5.00 net.

This charming book is a collection of addresses, lectures, and essays that have been published at various times during the last few years. The author dedicates the volume "To Dr. W. H. Mayo, Dr. C. H. Mayo and my friends at the Mayo Clinic. A small acknowledgment of a great debt." The first essay is the well known Murphy Memorial Oration which is already familiar to many American readers. The second essay is entitled "The ritual of a surgical operation" and it should be read by every surgeon. Most of us will readily admit the truth of the statement that "every operation in surgery is an experiment in bacteriology". There follow essays on "The Diagnosis and Treatment of Chronic Gastric Ulcer", "Disappointments After Gastro-enterostomy", "Intestinal Stasis", "Acute Emergencies of Abdominal Disease", "The Gifts of Surgery to Medicine", "The Surgery of the Chest in Relation to Retained Projectiles" and "The Most Gentle Profession". Probably the most interesting of these essays is the one entitled "The Gifts of Surgery to Medicine" which was the annual address in surgery delivered before the British Medical Association. It is obvious that Moynihan is an admirer of American medical men.

VICE AND HEALTH. PROBLEMS—SOLUTIONS. By John Clarence Funk, Director Bureau of Protective Measures, Pennsylvania State Department of Health, Scientific Assistant U. S. Public Health Service. Philadelphia and London: J. B. Lippincott Company. Price $1.50.

This book of 174 pages is dedicated to the League of Woman Voters. It has a yellowish-green cover with the legend, in red, "How to Put the Red Light Out". The book may be described by the stock phrase, "Well written". It deals with the different aspects of prostitution, but develops no new theories. It should most certainly be read by those to whom the author has directed his appeal.

CALCREOSE

"CREOSOTE and * * * * are used internally as intestinal and urinary antiseptics, as stimulant expectorants and in the treatment of tuberculosis. Their local irritant actions often interfere with their internal administration." (New and Nonofficial Remedies, 1921, p. 89.)

CALCREOSE is a mixture containing in loose chemical combination approximately equal weights of creosote and lime (calcium creosotate.)

CALCREOSE administered internally has the same actions and uses as creosote, but does not readily produce gastric distress, nausea and vomiting even when large quantities are taken for comparatively long periods of time.

CALCREOSE may be given in the form of solution or tablets.

FUNCTIONAL DISEASES OF THE NERVOUS SYSTEM IN SOLDIERS AND CIVILIANS.*

CHAS. G. BEALL, M.D.
FORT WAYNE, INDIANA

It has been maintained that there is no such thing as a pure "neurosis", that there is always an organic or chemical change in the body giving rise to all signs and symptoms. The present tendency is to explain many symptoms, and symptom complexes, on the ground of disturbances of the function of the glands of internal secretion. We must not be conceited enough to believe that our present age originated this attractive theory, as the Greeks many centuries ago believed that the uterus had much to do with a certain functional nervous disease. In fact the name of this organ is given to the disease—hysteria. Another modern explanation for what many of us are wont to call functional nervous diseases is that they are dependent on disturbances of the sympathetic nervous system, of which we probably know less than of the glands of internal secretion. I do not mean to belittle these theories, because they stimulate much work, both experimental and clinical. Focal infections have likewise come in for their share of blame, and at times very properly, but many teeth and tonsils have been sacrificed needlessly, and subsequent events have proven that I have been the high executioner in not a few instances. At this point permit me to digress for a moment and call your attention to the fact that early in the lives of some of us the text books grouped together under the title of "functional nervous diseases", what to us are strange bedfellows. The older classifications included diseases which we no longer regard as functional, and there was a distinct tendency to group cases under the predominating symptom or the organ which apparently gave rise to the subjective symptoms. As an illustration of this I quote the following chapter heads from "Functional Nervous Disorders" by C. J. Jones, 1870: Tetanus; Chorea; Puerperal Convulsions; Acustic Neuroses; Pulsation of the Abdominal Aorta; Uterine Neuroses.

Bacteriology has removed some from this classification, a better knowledge of the function of the glands of internal secretion has removed another, and chemistry has removed another. The modern conceptions and present experimental methods may, and undoubtedly will, remove others. I take it that the modern conception of a functional nervous disease is one in which certain, usually subjective, sensations are present, for which, after a very thorough examination, no definite explanation can be offered.

In the last seven hundred cases examined in my office, approximately one out of seven cases came under this general heading, the various types being as follows:

Pseudocyesis, 0.1%; intestinal neurosis, 1.7%; neurasthenia, 1.5%; neurosis (not defined, including anxiety neuroses, traumatic neuroses spasmodic tic), 8.4%; hypochondriasis, 0.87%; psychasthenia, 0.28%; hysteria, 1.4%. This proportion of cases is probably rather high for the reason that I see most of the ex-soldiers in our district who have functional or organic nervous diseases. It may be said that some, or possibly all, of these cases have some undiscovered organic basis, but each one received a thorough study and the diagnosis was not made when any evidence of organic disease was found.

The importance of using every means of excluding organic disease cannot be too strongly emphasized. This must include a careful history, a thorough and complete physical examination, and such modern laboratory examinations as are indicated. A brief review of the predisposing factors may not be out of place. Heredity, no doubt, plays an important part. How often do we find in the family history that the father or mother was "very nervous", but on the other hand, histories of definite psychoses in the parents is rather rare. Probably the chief, predisposing factor is a recent acute infectious disease. How often do we hear "ever since I had the 'flu'," "flu" of course

*Read before the Medical Section of the Indiana State Medical Association at the Indianapolis session, September, 1921.

covering a multiplicity of acute infections. Trauma, both physical and mental, is the starting point in many cases. The physical traumas, of course, play a great part as an etiological factor in soldiers for two reasons; first, the unusual nature of the trauma; and, second, the individual was probably exhausted physically, and also under great mental strain when the trauma occurred. It is a rather prevalent opinion that soldiers suffer from altogether different types of functional nervous disorders than civilians, but such has not been my experience, with one exception, and that is the extreme type of traumatic neurosis. Physical traumas occurring in civilian life can produce the same effects, even when they are non-litigation injuries. Surgical operations are a not uncommon source of this type. Of course, an ill advised operation on an already neurotic individual is sure to lead to disaster, but, at times, we see neuroses following imperative surgical procedures. Of the psychic traumas, deaths of near and dear relatives and prolonged mental strains are frequent predisposing factors. I believe that lack of variation in work has to do with producing neuroses in males of keen mentality in a vast majority of cases. We have Freud to thank for presenting to us, forcibly, the part that repressed wishes and desires have in inducing subjective sensations. I want to preceed what I next say with the emphatic statement that true malingering has been exceedingly rare in my experience, but the subconscious knowledge in either soldier or civilian that disease or injury is compensable is a factor in bringing a latent neurosis to full life and maintaining it. One more factor must be spoken of, and it is of great importance because it is preventable. I refer to suggestion. It not infrequently happens that a young male will become conscious of an extra systole, or a few forcible heart beats. He goes to a physician for advice, and because the nature of the subjective sensation is not understood, or because there is a soft systolic murmur, the patient is told he has heart disease and a neurosis is established which may take a year or longer to recover from. Gastro-intestinal symptoms dependent on constipation, faulty habits of eating, or lack of exercise may arouse the suspicion of cancer or ulcer, and if the patient receives a hint of this, the uncertainty and doubt which is established upsets the balance wheel.

Obviously to establish the diagnosis of a functional nervous disease means a thorough study of the case. The doctor who has probably watched the individual develop from childhood, knows his family life, and has cared for his or her parents, has a better insight into the predisposing factors than anyone else. As the diagnosis is based largely on exclusion, only general statement can be made in regard to methods. Brown-Sequared, in his lectures on "Functional Nervous Affections" published in 1868, states that the distinguishing characteristics of a functional nervous affection are "great variability in the intensity of the symptoms, and regular or irregular attacks, with intervals of almost perfect health between these attacks." The minor stigmata of hysteria such as conjunctival anaesthesia, loss of pharyngeal reflex, areas of anesthesia, or contraction or inversion of the color fields are not infrequently encountered. The effort test, i.e., noting the pulse rate at rest, after fifty hops, and after two minutes' rest, will differentiate a neurocirculatory asthenia, but it may require a determination of the basal metabolism to differentiate this from a hyperthyroidism. Rapid exhaustion, following physical or mental effort in an individual who looks well, is suggestive.

The first step in the treatment of functional nervous diseases is the establishment of a definite diagnosis, and where this is done the confidence of the patient has been gained and then the condition should be explained in the simplest of terms and confident assurance that a cure can be obtained. The details of treatment will follow three general lines, the moral, physical and last, and least, medication. A definite congenial occupation is a prime necessity, and even an uncongenial occupation may be made more acceptable by varying it with intervals of a change of work. Only in exceptional cases is it advisable to have the individual stop work, and when this is necessary it should not be for prolonged periods and this applies especially to soldiers. For instance, the office man may be induced to become an amateur farmer or florist out of hours, or the mechanic may be induced to take up a correspondence course. In the case of a woman the problem is a more difficult one, and often taxes the ingenuity of the physican to the utmost. While for the well-to-do patient, hydrotherapy in well appointed establishments is available, yet much benefit can be derived from the more simple home hydrotherapy. Warm and cold sponge baths and salt baths followed by vigorous rubs can be taken in any home. The exercise and increase of moral tone induced by competitive and semi-competitive games are of immense benefit. Stated rest periods for women "whose work is never done" are of as much importance as the outdoor exercise for the "desk" man. In the gastro-intestinal neuroses an abdominal support, whether it corrects a visceroptosis or has some other obscure influence is weil worth trying. Of dietery modifications I will mention but two, because of their importance. First, an effort should be made to increase the underweight individual, and, second, it is ten times

better to correct the frequently co-existing constipation by diet than by drugs, though these may be temporarily necessary. A list of drugs used in the treatment of functional nervous diseases would include almost the entire pharmacopeia, and the list is being added to each year. A few non-narcotic nerve sedatives have stood the test of time, and of these the bromides are probably the most important. In this connection it is well to remember that most potassium salts are more toxic and depressant than the salts of other metals, and had best be avoided. Our forefathers found out emperically that belladonna was of benefit in certain nervous disorders. We now have possibly more rational grounds for its use, as Eppinger and Hess have apparently shown that certain so-called "nervous individuals" suffer from a sensitization or hyperexcitability of the vagotonic system, and atropine lessens this excitability. I hesitate to say anything about glandular therapy because I have been unable to clearly establish in my mind the indications for their use, in spite of rather close study of current literature and a good deal of experimental administration. To be perfectly frank, I recall but one case in which the results were highly satisfactory, and I am unable to explain the rationale in this case. Fortunately, with the exception of thyroid substance, none of them so far as I know do harm, so clinical experimentation is safe. In these clinical experiments, in order that they may be of real value, the various gland substances had best be used singly or at most in combinations of not more than two.

In conclusion it can be said that for the successful treatment of functional nervous disorders the physician must have a broad knowledge of clinical medicine, much patience, and a good fund of common sense.

DISCUSSION

DR. W. D. ASBURY (Terre Haute): I have been trying to make a study of these functional cases, and it is very difficult to satisfy one's self about some of these things. Just recently I had a case that I had occasion to go over, since Dr. Beall asked me to discuss this paper, in which I had to make a diagnosis of neurasthenia. I went back and tried to work out that case better because I always hesitate to make such a diagnosis. This case is a pulmonary tuberculosis with the so-called functional syndrome.

I would insist that we, as medical men, especially those of us that are trying to do internal medicine, have our patients strip and go over them thoroughly so that we may hear every sound of the lungs, and we should spend at least an hour on such patients. I think we cannot properly examine a patient in less time than that. It may be that in some of these functional cases we may not be able to find anything definite, as in the cases Dr. Beall has mentioned. I do think that in these psychic and mental types there is something, somewhere back in their lives, consciously or subconsciously, which is responsible for the present symptoms. If we could go back and find the little thing, the repressed wish or desire that eventually creeps out and produces all these symptoms; and if we were astute enough to analyze it and bring it out, we might be able to help some of these patients. By knowing their mental qualities we might be able to get rid of some of the unsatisfactory diagnoses which we are forced to make.

In regard to treatment, the best thing is to take the individual out of his environment and let him become so interested in something which he wants to do that there will be no time to think of himself, and thus he may develop vision and mental stamina enough to go through life without great handicap.

DR. CHARLES D. HUMES (Indianapolis): Shortly after my return from France, I published a very short paper covering several thousand cases of "shell shock" under the title of psycho-neurosis, manifesting psychoses, paraplegia, monoplegia, mutism, deafness, hysterical contractures, etc.,—one big classification. I thought it was easy to cure them, as conditions existed in France. Out of Chateau Thierry we received eight hundred men who could not walk or talk, who had tremors and all that. Within two weeks all but fourteen of them were back in the line *being shot at for eighty cents a day.* How did we do it? We talked to the men and got to know them, know where they came from, and so on, following the motto of "Get your man,"—know where he comes from, get his confidence, find out what happened—was he blown into the air, did he sleep in the mud for a couple of hours before he was found, did he nearly drown in a concealed shell hole—get his story from him. Then you become acquainted with his experience, and as he unfolds, you carefully replace the unpleasant part with a satisfactory explanation, which has for its purpose *making the cure a mentally painless* one.

There is a particular type of functional disorder which has an organic manifestation, described by Babinski. I could not believe that a man could have a functional disorder with organic manifestations until I saw a soldier diagnosed Raynaud's disease, with his arm utterly helpless in a sling. *With the stage all set,* we examined this man who could not move his right arm, and I suddenly saw in moving his left arm that function had returned in the right. Then I began treatment, talked to him and told him anything I thought would help—I believe you are justified in telling a patient

anything if you are honest—so I told that patient of the cures of others and had him recovering, using his arm and hand slightly, when one day an officer (regular) came through the ward and roughly said: "How many malingerers have you got in here?" Back came the swelling in the boy's arm and today he is in the government hospital with all those original symptoms. That is purely an arrest of the voluntary cerebral center manifesting loss of motor function with profound vaso motor paralysis, swelling, blueness and coldness of extremity.

DR. CHARLES G. BEALL (Fort Wayne) (closing): In closing I have just a little heart to heart confession to make. When I have finished a case, or think I have, I always try to come to some definite conclusion and put down a definite diagnosis, but sometimes that has to be "unknown." I have a card in my desk which means mistaken diagnosis. I do not mean to say that I know all the cases in which I have been mistaken, but whenever I find that I have been mistaken, I put that case down. I am not going to say how many I am mistaken in, but approximately one-half of the cases in which I have been mistaken are those in which I have put down the diagnosis in the psychoneurotic group.

FOREIGN BODIES WITHIN THE RESPIRATORY TRACT*

MAURICE H. KREBS, M. D.
HUNTINGTON, INDIANA

In presenting this subject before this section, the essayist is mindful of the fact that his own personal contribution to this special field of medicine has indeed been comparatively small. The writer's interest was forcibly attracted to and his attention held by several personal instances of obscure, severe and long standing pathologic pneumonic conditions, which were cleared up entirely in so far as their etiological factors were concerned, and in which the subsequent therapeutic measures, along practically new lines, were productive of remarkable results.

Even a casual excursion into any field of medicine reveals the regrettable fact that we sometimes fail to make any diagnosis, and that not infrequently our mistakes in diagnosis are revealed upon the autopsy table. Cabot of Boston has given us ample testimony as to the accuracy of this statement. This in part is due to our failure to avail ourselves of the most modern methods of arriving at a positive diagnosis. The employment of the radiograph, fluoroscope, the bronchoscope and its adjuvants, has to an enormous extent aided in the diagnosis of pathological changes in the lungs, clarified their etiology, and pointed toward a more direct therapy. However, even very recent medical literature is replete with records of lung and bronchial affections following the inspiration of foreign bodies, the presence of which were either unsuspected or undiagnosed.

Broadly speaking, a foreign body within the respiratory tract should be considered as anything which normally does not belong there. Here should be included almost every conceivable substance, whether metal, mineral, vegetable or animal. Immediately upon the inspiration of a foreign body, or shortly thereafter, symptoms appear in accordance with the size, shape, chemical composition, character, position and point of lodgement. Here permit me to say that a diphtheritic membrane, laryngeal or bronchial, should always be regarded as a foreign body, which by location, shape and size may produce marked dyspnoea and often fatal asphyxia. A foreign body retained for any length of time may act as a mechanical irritant *per se*, and having reached a final point of lodgement, produce a slow destruction of surrounding tissue as the result of chemical changes, pressure necrosis, or bacterial invasion accompanying the foreign body. While this is true in the vast majority of cases, to prevent controversy, it should also be stated that there are a number of authentic records of foreign bodies *in situ* for even months and years, leaving no pathology which can be demonstrated by radiograph or physical signs.

The symptoms of cough, fever, dyspnoea, hemoptysis, sweats, loss of flesh and strength and so forth, all give a syndrome pointing toward tuberculosis, and after a study of the literature, and from my own personal observation, I am fully in accord with Boyce in believing that there have been a considerable number of authentic and recorded cases of supposed tuberculosis in which unsuspected foreign bodies were coughed up, or removed, with resultant cure. The earliest report that I have been able to find is that of Dr. Arnot, who in 1742, before the Obstetrical Society of Edinburgh, gave the history of a case of consumption cured after coughing up a bone. In 1786, Wells, in the *London Medical Journal*, gave the history of a case of pulmonary consumption in which all the symptoms were suddenly relieved by the expectoration of a carious bone, and the patient went on to a rapid recovery. Through the succeeding years others have reported similar instances. It is not within the scope of this paper, nor do I desire to burden you with the citing of these early cases. I have appended a bibliography and reference for those who are

*Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

sufficiently interested. It should be noted, however, that before the advent of the x-ray, the fluoroscope, and the bronchoscope, these foreign bodies evidenced themselves only through cough, expectoration, the breaking down of tissue or post mortem. Since the more frequent use of the above aids, there are a great number of records of foreign bodies within the respiratory tract which have caused pathological conditions closely simulating tuberculosis, and which conditions cleared up promptly with the bronchoscopic removal of the foreign body.

Killian, Jackson, Mosher and others have remarked upon the rapid recovery of lung tissue, even when the suppurative process had extended over a long period of time with large areas involved. In 1913 Jackson reported a very interesting case in which a glass collar button had been retained in the lung for twenty-six years. At the time of the removal of the collar button by bronchoscopy, this woman had as a result of her septic condition been reduced in weight to ninety-eight pounds. In two years she had regained perfect health and normal weight. In March, 1919, Jackson, commenting on this case, reported her weight as one hundred and eighty-two pounds.

Mr. J. W. B., fifty-eight years old, had for a year and one-half been suffering with a chronic bronchitis, with very severe exacerbations from time to time. He had been under treatment in a sanitarium, and had improved considerably. Recurrence of his bronchitis resulted in a fluoroscopic examination which showed a darkened area about the root of the right lung, which was attributed to calcified glands. Finally a radiogram was made which showed a foreign body. This was removed by Jackson, and proved to be the metal tip of an atomizer, which the patient recalled having used. Prompt recovery followed.

Under my own personal observation, came a patient of Dr. W. F. Smith, of Huntington. John W., a boy of fourteen, had for years been suffering with a constant cough with purulent expectoration in large quantity. At the age of six he had a pneumonia, but did not make a good recovery. His cough continued, and he expectorated large quantities of very foul smelling pus. His symptoms and physical signs were very suggestive of a pulmonary tuberculosis with abscess cavity. Frequent examinations of his sputum failed to show tubercle bacilli. His guardian, hearing by accident of another patient being cured of a similar condition by the finding and removal of a foreign body from a lung, remembered that John at the age of four was supposed to have swallowed a collar button, although there were no immediate symptoms, and it was supposed that the button had passed into the stomach and then on through. A fluoroscopic examination followed by a radiogram, immediately disclosed the button, which was removed by Jackson, with the resultant prompt cure of his condition.

In support of the belief that foreign bodies in the respiratory tract be removed as soon as possible after discovery, I desire to refer to one case reported by Jackson in the Mutter Lecture before the College of Physicians of Philadelphia in 1917. In doing so I want to pay my personal respects to the pioneer in America in this work. Those of us who have been so fortunate as to see Chevalier Jackson in action, have often marveled at his uncanny skill and dexterity. The case just referred to was that of a woman who for many years went seeking health from sanitarium to sanitarium for what was diagnosed as pulmonary tuberculosis. She was brought into the hospital almost dead from repeated hemorrhages and sepsis, as the result of an open safety pin, which was present in the right bronchus. The presence of this safety pin had been known to her physician five years previous, when a radiograph was made, but he had advised against its removal, preferring "to let well enough alone." Jackson made no attempt to remove this pin at the hospital, owing to the patient being *in extremis*, dying the next day.

To intelligently interpret the pathological processes and their production in the respiratory tract by foreign bodies, one must constantly have in mind its anatomy and physiology. Time will permit me to recall to your attention only a few features of the gross anatomy and gross physiology, only enough to serve as a basis for my remarks. At this time let us leave out of consideration the mouth and pharynx, and visualize with me a tube beginning as the larynx, continuing as the trachea, and then bifurcating into a right and left bronchus, the right bronchus dividing itself into three smaller bronchi to serve the upper, middle and inferior lobes of the right lung, the left bronchus dividing itself into two smaller bronchi, to serve the superior and inferior lobes of the left lung; that when these smaller bronchi enter the various lobes, this division and subdivision into smaller and smaller bronchi and bronchioles continue almost to the periphery of each lobe, the entire process in completion, being likened to a tree with its numerous branches and stems, therefore appropriately known as the laryngeo-tracheo-bronchial tree. As a result of this anatomical arrangement, it is evident that each bronchiole serves, brings air to, and drains only a small roughly triangular portion of lung tissue. At the upper end of the larynx we have the vocal chords, whose approximation in the median line and free movement gives rise to phonation, as the direct result of a column of air from below, setting them in vibration. This

presupposes that nerve and other conditions are normal. The gross physiological function of the laryngeo-tracheo-bronchial tree is that of providing a mechanical means for respiration. In addition the entire bronchial tree acts as a means for drainage of secretions, the act of drainage being facilitated to some extent by the upward movement of the mucosal cilia.

Now visualize a foreign body lodged for a length of time anywhere within the respiratory tract. We note the possibility of a stenosis, either partial or complete, depending upon the size, shape and manner of lodgement. If the foreign body be lodged above the bifurcation, there is a greater probability of interference with respiration than if it be situated below the bifurcation, since in the latter event one lung would still be receiving air—in fact would gradually become compensatory in function and action. Yet very large objects like coins and pieces of bone, large enough in themselves to completely block off the respiration, have lodged in the larynx or in the trachea, but owing to their position have allowed air to pass by. In the larynx, especially high up, the foreign body may produce difficult and painful deglutition and cause interference with the voice amounting sometimes to a total aphonia.

The foreign body may lodge in one of the main bronchi or pass into one of the smaller bronchi or bronchioles until it has found a place of lodgement. Wherever that may be, some local pathology will ensue. The foreign body, *per se,* acts as a mechanical irritant. It may react chemically toward the tissue, or the secretions may cause corrosion of the object, roughening its surface, thus further increasing its irritative effects. Acute inflammatory conditions may be set up by the movement of the foreign body by respiratory activities, until it has become more firmly imbedded. In this movement, especially if the object be pointed or sharp, the lining membrane may be traumatized and saprophytic bacteria introduced beneath the mucosa. The lumen may be occluded, the stenosis being complete or partial; if complete stenosis, the roughly triangular portion of lung served will be practically "corked up"—air shut off—a condition of atelectasis, the secretions dammed back, and that part of the lung may be "drowned in its own secretions"; if partial stenosis, there will be some interference with drainage, inflammation, granulation tissue, further increase of the stenosis, a bronchitis, dilatation of the bronchus,—a condition of bronchiectasis. There may be the production of a pneumonia or broncho-pneumonia, the latter more frequent in young children. We may have an interlobular emphysema, the result of trauma, and of powerful efforts at inspiration, the air entering the connective tissue of the septa between the lobules of the lung. Or we may have a vesicular emphysema, which is really a compensating phenomenon, and it means that if one lung or a part of one lung is so changed by pathological conditions, that it can only partially perform its functions, the other lung becomes increased in size and its air spaces are dilated. In my opinion this form of emphysema should not be regarded as a morbid condition. This change in the lung is a healthy one—an act of compensation. It produces no symptoms of disease, although it can readily be detected by physical signs and auscultation. In the same way, but on a smaller scale, whenever portions of the lung are consolidated by chronic changes, in other portions we find areas of dilated air spaces. Further pathological conditions produced are that of abscess cavities, pneumothorax, pyopneumothorax, haemothorax, empyema, and gangrene.

To Dr. H. L. Lynah of New York belongs the credit of calling attention to the presence of diphtheritic membrane, either primary or secondary, within the trachea or bronchi, and the treatment of tracheo-bronchial diphtheria bronchoscopically. I am indebted to him for the substance of the following remarks. In a paper read in 1916 he conclusively showed that a diphtheritic membrane may be lodged within the trachea or bronchus and act as a foreign body, occupying a part of or the entire lumen, thus partially or completely obstructing respiration. The resultant condition is sometimes erroneously diagnosed as a broncho-pneumonia. Lynah believes that not infrequently these cases are primary. They are accompanied by marked dyspnoea and cyanosis and give the physical signs of bronchial stenosis. Inasmuch as in these conditions no nasal, tonsillar or pharyngeal exudates are present, cultures from the throat for the bacillus of diphtheria are negative. The clinical picture is that of a gradual onset, slight occasional cough and roughened breathing. It resembles a slight cold. With such a slight symptomatology, many of these conditions are overlooked, unless a membrane is coughed up, or the larynx becomes involved followed by a typical attack of "croup." As the obstruction continues there is a marked emphysema of the lung in which the bronchus is obstructed, the foreign body acting as a valvelike mechanism, permitting more air to enter the lung than can escape. Lynah states that inspection shows a barrel shaped chest on the side involved, retraction above the clavicle and in the sternal notch, and sinking in of the epigastrium. Cyanosis of the finger tips is a constant sign. The percussion note is that of increased resonance. Auscultation reveals diminished or absent respiratory sounds of the affected side, especially when compared with the harsh

breathing of the other side. Rales of all kinds may be present. There is also sometimes present that peculiar "flapping" sound produced by air passing back and forth over the flapping membrane, when the membrane is partially loose. These cases become very clearly defined, because they are unsuccessfully intubated with the longest O'Dwyer tubes, indicating that the membrane or maybe edema is below the lower end of the tube. The treatment of these conditions is early recognition, antitoxin, and prompt removal by direct tracheoscopy or bronchoscopy. I have no faith in tracheotomy where intubation with the longest O'Dwyer tube has failed. I admit of necessity, that one can through a tracheotomy opening swab the territory below, and occasionally insert a forceps and bring up a membrane. But that is working blindly, and in the dark, and is unscientific. I am in accord with Lynah in believing that when a tracheotomy in a case of tracheo-bronchial diphtheria is not successful because the longest O'Dwyer tube is not long enough to reach below the obstruction, that tracheoscopy or bronchoscopy with removal of the foreign body membrane is indicated. This removal can be effected by forceps or suction through the bronchoscope, the suction being applied through a metal tube connected with one of the various electrically driven vacuum pumps. With the use of the forceps there is a greater tendency toward bleeding. With the suction method, there is less liability for this to take place. The bronchus should be swabbed with antitoxin. The risk of this procedure either in children or in adults in these cases is slight. No anaesthesia, local or general, is required. This treatment by Lynah has proved of inestimable value as shown by the records of Willard Parker and Kingston Hospitals in New York City.

The symptomatology, physical signs and diagnosis of foreign bodies within the respiratory tract, depend upon the character of the object, and whether it be lodged within the larynx, trachea or bronchi. Within the time limit it is absolutely impossible for me to classify the various foreign bodies, and to differentiate their symptomatology and physical signs in accordance with their location. I can refer only to the most prominent features which should direct suspicion toward the presence of a foreign body.

At the time of inspiration of a foreign body there are usually immediate symptoms of irritation, obstruction, strangling, laryngeal spasm, and violent efforts of coughing to expel the intruding object. There are a number of instances in which there were no immediate symptoms of any kind at the moment of inspiration. As the foreign body passes downward, or is pushed down by digital examination or attempts at removal, the alarming symptoms of obstruction and strangulation are apt to grow less and even disappear, causing the erroneous belief that the object had been in the oesophagus and had passed into the stomach. Here I should call your attention to the anatomical condition of the lumen of the trachea being larger than that of the larynx, so that an object within the larynx, causing alarming symptoms of obstruction, may readily pass into the trachea with marked improvement in respiration with partial or even total subsidence of initial symptoms. Additional symptoms may be pain localized at the point of lodgement, painful and difficult swallowing and impairment of voice.

When the object has passed into the trachea, the violent initial symptoms usually subside, and the patient is left with a "wheezing" respiration, or there may be a "flapping sound," which is usually distinctly heard over the trachea and a cough which comes on in paroxysms, and may be very violent. As the result of such efforts at coughing and in addition the powerful expiration, the object may be forced up into the glottic chink and cause sudden marked dyspnoea and even asphyxia. Unless early relieved, a movable foreign body may produce edema and trauma of the tracheal mucosa with consequent additional obstruction and probable infection.

The symptomatology of foreign body within the bronchi has been indicated in my earlier remarks. It is important to remember that when a foreign body has reached a bronchus there may be a cessation of symptoms for weeks and even months, depending upon the nature of the invader, the age and resistance of the patient. Pain may be present or absent. The train of symptoms, although not always constant, is that of cough, cyanosis, fever, sweats, expectoration of large quantities of very foul smelling pus, hemoptysis, and loss of flesh and strength. Physical signs depend to a great extent upon the length of time of sojourn, and the mechanical element. We see contraction of the side of the chest involved and expansion of the other—limitation of respiratory movements, clubbed fingers and clubbed toes—indicating an interference within the lung of the aeration of the blood. Percussion and auscultation elicit sounds varying with the pathology, and has already been considered. As Jackson concretely puts it, "periodic attacks of fever, cough, chills, and sweats, followed by increased coughing and the expulsion of a large amount of purulent, usually more or less foul material, are so nearly diagnostic of foreign body, as to call for exclusion of this probability with the utmost care." And I add to this statement, "especially when frequent examination has failed to demonstrate tubercle bacilli."

To arrive at a diagnosis, the history of the accident, when one can be obtained, must be carefully considered. Frequently there is no knowledge of having inspired a foreign body. When suspected, we should immediately avail ourselves of the fluoroscope, radiogram and bronchoscope. Both frontal and lateral pictures should be taken, as occasionally the shadow of an opaque body will fall within the shadow of the spine and not be seen. In non-opaque bodies, the shadows of the pathological conditions should be carefully studied and compared with the physical signs, and those elicited by auscultation. The bronchoscope should be used for diagnosis, the operator being always prepared for the removal of a suspected object.

For treatment in these cases, there is but one indication—that of removal by bronchoscopy. The risk is slight—not at all to be compared with that of pneumotomy, in which the mortality is close to one hundred per cent. There are practically but few contra-indications—chiefly aneurism, exhaustion and moribund conditions. Jackson in his statistics gives his results in over eight hundred cases as ninety-one per cent successful for removal and cure. Removals have been performed by bronchoscopy under fluoroscopic control. Hickey of Detroit was, I believe, the first to make use of the "giant magnet," applying the same to the chest wall, dragging a closed safety pin from the lower bronchus up through the air passages and delivered by means of a tracheotomy opening.

In this connection it might not be out of place to state that in March, 1921, Lynah and Stewart of New York reported a method of mapping out lung abscesses by means of injections bronchoscopically of sterile mixture of bismuth subcarbonate in olive oil, injecting slowly eight c.c. of the mixture one to two parts, followed immediately by fluoroscopic examination and radiogram. This mixture is harmless, soon passes out and while apparently of no therapeutic value, improvement has been noted in the cases in which it was used. This method opens up a field of study which certainly will be of help to the thoracic surgeon and has great possibilities for the internist and bronchoscopist.

In conclusion, I would like to say that this paper is but an humble effort to direct attention to the more frequent use of these most modern agencies in diagnosticating some of our obscure and long standing pulmonary cases, especially those in whom a specific causative factor cannot be demonstrated. The bronchoscopic treatment of tracheo-bronchial diphtheria should merit your attention and investigation as a means of saving lives.

DISCUSSION

DR. ALFRED HENRY (Indianapolis): As indicated by the subject of the paper, we know that foreign bodies produce many different types of pathology. Lodged bodies may produce pathology anywhere in the lung, in lobules or in the whole lobe, or the right or left bronchus. You can see how we can get gangrene with a foreign body in a small tube. We have a laceration, with inspired circulation and respiration, next we have infection and the respiratory tract nearly always responds to that, so it is easy to see how a foreign body can produce abscesses or gangrene. If a foreign body obstructs a bronchial tube the air that gets in will dilate, this causing bronchectasis. In fact, one of the first things that is produced is a capillary bronchitis. The foreign body produces a condition that carries with it a good deal of exudate and that is responsible for the rales. Then if we have some foreign body that is sharp and cuts, which subjects the tissue to further insult, trouble is more surely to be brought about.

The gist of the paper seems to be diagnosis, and when we come to diagnosis we have to differentiate and thereby hangs the story of a great many cases. You have bronchiectasis, empyema, a pleurisy with effusion, and gangrene of the lung—you have all these to consider in differentiating. Of course, the first thing is the history, but the essayist says that in some of these cases there is no history. I say we must get down to brass tacks and go clear to the end in this history taking. I take it that everything in the way of disease has some symptoms that aid in making a diagnosis. When we are in the field of pathology we have many indications. In tuberculosis we have red letter signs—we talk about the hemorrhage, but I think we do not have excessive hemorrhage from foreign body cases. We do not necessarily have a feeling of malaise, which is the first symptom of tuberculosis. We do not have tubercle bacilli, we do not have the tuberculin reaction, we do not have complement fixation in the foreign body, but we do have the x-ray, thus we have two or three red letter symptoms in the diagnosis of foreign body. If we will take these red letter symptoms and work them out we can go further along in the diagnosis, and that is the most important point.

DR. C. A. SELLERS (Hartford City): It would seem to me from the standpoint of a general medical man, that the question should hinge on a correct diagnosis, as the previous discussant has stated. I do not believe that the x-ray findings can be absolutely relied upon, except in reliable and experienced hands and then in conjunction with the clinical findings.

There is one point in this paper which I think demands our careful consideration, and, what

I wish to say on this point is not from the standpoint of criticism but from the standpoint of conservation of our patients; that is in advocating the use of the bronchoscope in broncholaryngeal diphtheria. Those of you who have seen broncho-laryngeal diphtheria (which is usually diagnosed as a broncho-pneumonia), especially if this diptheretic membrane is quite complete, will certainly hesitate to advocate the passing of a bronchoscope. It may be safe in the hands of the very expert to lift out a free membrane that has lodged in the larger bronchus, but when you have evidence of a diffuse broncho-pneumonia one had better depend upon his antitoxin.

DR. JOHN F. BARNHILL (Indianapolis): It has already been pointed out in the discussion which has preceded that there has been an unaccountable inertia on the part of many in the profession concerning foreign bodies in the lung. This is unfortunate, because no class of ailment requires more prompt, more intelligent or more efficient attention than this. It is only by early, intelligent service on the part of the physician that actual tragedy is averted. It has been my misfortune to witness such tragedies. It also has been my supreme joy, with the efficient cooperation of attending physicians, to remove many foreign bodies and to see the patient live on. Often the most serious obstacle to successful removal is a delayed, mistaken or uncertain diagnosis, or failure to make any diagnosis at all. This is usually inexcusable. X-ray service may now be had in the larger cities and towns, and by this means the foreign body may be discovered at once, especially when metallic. The real trouble comes when the foreign body is organic, as a pea, bean or nut. It is in these latter cases that the services of an expert diagnostician are most needed. With the aid of this service and the history of the case as a guide, a correct conclusion may almost certainly be attained.

Within the past two weeks I have seen a case which exemplified the need of greater caution and interest on the part of the physician in the diagnosis of suspected foreign body cases. A child with a peanut in its mouth tried to go through a door, when the door slammed against him, startling him, and causing him to inhale the kernel of the nut into his right bronchus. The mother stated that the child struggled for breath, got blue in the face and nearly died. He then recovered somewhat but was not as before, breathed badly, would not play, and wished to be held in the arms constantly. When the child walked or otherwise exercised he was greatly distressed by cough and impaired respiration.

The above history is pretty typical of what occurs in nearly all cases of inspired foreign body. Keen physicians should suspect the real cause in all such cases, and should give the most painstaking and thorough examination to ascertain the facts. Many who inhale foreign bodies die in the first paroxysm, and within a few minutes. Should they survive, however, patients often seem more or less normal after a time, except when they exercise. It will be apparent to the observing physician that they are not normal, and a painstaking examination of the lungs will detect the reason.

The doctor first in charge of the case here described expressed the belief that there was nothing serious and that all soon would be right. Another physician was consulted, and while he believed the case not serious was yet cautious enough to advise an x-ray examination. The child was brought to the Methodist Hospital, where plates were made which showed collapse of the right lung.

While we were in the surgery with everything ready to do a bronchoscopy word came from the child's room in the hospital that he had died from sudden suffocation. Evidently he had coughed the peanut from the completely obstructed bronchus and then immediately sucked it into the only open one.

The time certainly has come when foreign body cases should be more frequently and promptly recognized. Both physicians and surgeons are always alive and active in the early diagnosis and operation of appendicitis, gall stone and other abdominal cases. This cannot be said of them in foreign body cases as yet. One of the discussants has intimated that patients suffering from foreign bodies in the air tract have been sent to climatic resorts in the belief that the case was tuberculosis, and that such failure to proper diagnose is a disgrace. Of course it is, and is below the high standard of Indiana medicine. It is because of indifference, not ignorance. But since the result is the same, there should be an awakening to the importance of the subject.

DR. KREBS (closing): I wish to thank the gentlemen for the kind reception of this paper. It is true as Dr. Henry stated in his discussion that a history is not always present. He doubted if it could be obtained. It has been my experience that you can usually obtain a history in a case of voluntary inspiration of a foreign body. In the involuntary variety, there may be no history; especially is this the case in those of unsound mind, and in those patients addicted to the use of drugs. Dressmakers who are in the habit of holding numerous pins in the mouth while fitting are unable to state whether a pin has been lost or not. Pins have been known to go down head first, without any immediate symptoms, thus making the diagnosis more difficult.

In regard to the x-ray, it is not always to be depended upon. A tooth will not always give a picture. Again an opaque body may fall within the shadow of the vertebral column and will not show.

Dr. Barnhill's discussion proved very conclusively and dramatically how easily and rapidly a child may be asphyxiated by a foreign body being coughed out of the bronchus of the already completely closed lung, and immediately inspirated into the other lung.

The question of doing an intubation, a tracheotomy or bronchoscopy in diphtheria, depends to a large extent upon the location of the membrane. If the membrane is situated low down within the larynx, you may not be able to push it aside even with the longest intubation tube. The length of the intubation tube used is limited by the size of the mouth. If the results of the intubation are unsatisfactory, you may resort to a tracheotomy, with its attendant dangers. Yet through a tracheotomy opening you may be able to reach up or down and remove either the entire or part of the obstructing membrane. All of this can be easily accomplished by a laryngoscopy or bronchoscopy, and there is less danger of infection or trauma, and the risk is very much less than that of an intubation or tracheotomy performed by the average man. I still maintain and believe that the method outlined in my paper is perfectly justified and is to be indicated as a regular procedure especially when the membrane is low down.

GROUP MEDICINE DIAGNOSIS*

LEON L. SOLOMON, M.D.
LOUISVILLE, KENTUCKY

Mr. President, Members of the Fourth Councilor District Indiana Medical Society, Ladies and Gentlemen:

The writer recalls his wonder and amazement, when he first attended the Medical, Surgical and other Clinics at the Medical Department of the old University of Louisville, in the early nineties, and watched the professor "make the diagnosis". As he now reminiscences, he remembers the feeling of delight which overcame him when *he* first began to get a glimpse of the plan, the professor, in those days, pursued, in order to establish his diagnosis. He wondered then at the possibility of exactly knowing what was the matter with the patient and he was amazed at the idea of the professor's accuracy in the summing up of his opinion.

Almost thirty years have elapsed since these observations were made. In this long span of time much in diagnosis has been rewritten, but be it said to the credit of the men of those and earlier days, their work was so well done, the avenues by which they were to reach their conclusions were so carefully and searchingly explored and the plan so well executed, that we may largely depend, even in these more modern times, upon the same rules and regulations then in vogue, and feel assured that we are not far from the truth of a correct opinion.

When your president, Dr. D. W. Weaver, did me the honor recently to request me to address you this evening, I cast about for a theme which I might, with propriety, present, finally determining upon the general subject of diagnosis. Though there may be many and possibly much more alluring subjects for an audience like this, I felt that it might please us and maybe profit us to spend our time recounting, more or less in detail, the plan by which the modern day doctor approaches the accurate diagnosis of his patient's case.

To be a success at any work or any endeavor, one must understand what is before him. The successful farmer, the successful stock breeder and stock raiser, the successful plumber, the successful butcher, the baker or the candlestick maker, the successful preacher, lawyer, doctor, whatever the calling, vocation or profession, in order to succeed at it, he must know it and devote himself to it. If he does, there is no higher accomplishment than its successful performance, whatever it be. Among the very difficult tasks, which requires the highest order of intelligence and exacts the most untiring devotion to duty, none exceeds the calling of the physician, whose work deals with God's masterpiece—*man*. The complexity of the human organism and its mechanism, its masterful performance in health and its strange performance when diseased has occupied the best minds and best talents from the beginning of creation. Slowly but surely the veil has been lifted, and, one by one, the inner and more hidden recesses of the human animal have been explored and explained, until the medical man of the day, after examining the patient, as a whole, has been enabled, almost, so to speak, to disassemble the parts, interpret each separate part, and again to re-assemble the patient, even as the mechanic in the automobile industry becomes skillful in the disassembling and re-assembling of the machine.

Present Day Plan of Approach to the Diagnosis:

(1) History Taking.
(2) General Physical Examination.
(3) Special Examinations.
(4) Laboratory Work, including x-ray.

Each of the above divisions is further considered, divided and sub-divided as follows:

The History Taking. No part of the diagnosis is more important and requires greater skill, tact and patience than is necessary, in order to obtain a correct and dependable history.

*An address delivered before the Fourth Councilor District, (Indiana) Medical Society, at its annual meeting at Seymour, Indiana, May 25, 1921.

Not every physician is capable of obtaining a history. Indeed, I have frequently had patients say to me, "I could not tell that doctor *anything* about myself; he is too curt and too short and entirely too unsympathetic." Or I have had them say, "I wanted to tell the doctor how I felt and what was the matter with me, but he seemed to repel me, or he seemed to think he already knew all about me." To get the salient facts from the patient, as has already been stated, requires skill, tact and patience, neither more nor less of any one of these faculties and attributes, but surely much of all three. In our work, I have cautioned my associates to strain every energy and to bend every effort to discharge their fullest duty in *"the hearing* of the patient's story". We look upon the history taking as one of the most, if not the most, important single procedure in our effort to establish our diagnosis. Individual patients require individual handling in this as in other regards. Not every patient's history is to be obtained alike, but rather each patient's history is gotten after his or her particular fashion and liking. Some patients are loquacious, others are reticent, some are truthful, others are treacherous and deceitful, some are intelligent, others are stupid, some are easy and some are difficult. We never attempt to take a history hurriedly, but always aim to give all of the time necessary for its proper taking. We never feel that we have done justice to the history taking when we have devoted but one period of time to it, but rather prefer to go over the items, again and again, with the patient (or those accompanying the patient), and we like to do this on other days than the day the history was first taken. When the history taking is complete, we ask ourselves this question in the clinic, "In what direction does the history lead?" By this we mean, does it lead us to assume that the chief deviation from the normal involves (1) the Digestive System, (2) the Respiratory System, (3) the Nervous System, (4) the Skin, (5) the Genito-Urinary System, (6) the Osseous System, (7) the Joint System, (8) the Muscular System, (9) the Glandular System, etc., etc. Whatever may be the special direction or directions into which the patient's relating of his history leads us, we then undertake to develop this particular direction or the particular directions, by a special inquiry, studiously devoted thereto, a so-called "Special History Taking". In Group Medicine, as we conduct its practice in the clinic, we have found it well for several different members of the staff to take a hand in the developing of the history of each patient. We thus get important data previously overlooked.

History Sub-Divisions. Among these subdivisions may be briefly mentioned (a) Present History, which represents what the patient has in mind to tell the physician of his present condition. The present history is what actually brings the patient to consult the physician. Often this is all important, as for example, when it includes sudden departures from the normal, viz., chill, fever, sweat, general discomfort, with lancinating pain at the base of the right lung, cough and blood stained or brick dust expectoration. These are classical manifestations of a pneumonia and may be all the history that is available or need be obtained. In the vast majority of instances, however, we desire a carefully taken history of the preceding state of health, that is the health immediately preceding the beginning of the complaint. When the *status praesens* has been fully developed, (b) the Past History is inquired into. This includes all of the past, namely, from birth to the beginning of the present illness. We should know what diseases have been suffered, when they were suffered, how severe each disease was, what complications were present, and what sequelæ, if any, followed. We are interested in knowing *when* and *how often*, and *for what reason*, the patient was last in bed. The diseases of adult life, previously suffered, including the (c) Diseases of Infancy and Childhood, any and all may have a very positive bearing on the present ailment. In any event, the earmarks thereof may be looked for in the final estimate, which we will make of the patient.

Only the doctor who has taken pains to elicit every part and parcel of the history, past as well as present, including sometimes the seemingly most remote and insignificant facts, will succeed in adding that finer touch to history taking, of which Modern Day Diagnosis boasts. The patient whose train of symptoms leads us very positively in a certain direction will oftimes fail to tell the physician certain facts which have a most important bearing on his case. We must remember that the untrained mind of the patient in nowise fits him to make plain the salient points to the doctor. We must also remember that there are certain facts in the life history of patients which may have entirely escaped the recollection, but which will be recalled and sometimes vividly described, if we but carefully lead the patient back into the past.

I have in mind the history of a most intelligent patient, a man of culture and refinement, the trusted employee, throughout a period of fifty years, of a railroad and bridge company. When the gentleman first consulted us and a diagnosis of tertiary syphilis was made, he was wholly unable to accept it. There was no question in our minds as to the findings, though the history of the patient was deficient as to the date of any infection. He was a married man, past 65 years of age; his wife, living, and, though her health was not good and had not

been good for years, she presented no present evidence of a luetic infection; she recited no history that was even suggestive; she had been pregnant one time only, had had no miscarriages, had given birth to a healthy child, who in turn was the mother of a lovely, healthy, young daughter, some twelve or thirteen years of age. The patient himself had seemingly been in perfect health throughout all of his married life. Indeed, he could recall no illness of any sort whatsoever. Bilateral, palpable, discrete glands, absent knee jerk, Argyll-Robertson pupil, choke disk, unsteady gait, "gastric crises", positive Babinsky, together with a "four plus" Wassermann, made the Diagnostic Summary complete. Weeks after the man was under treatment, his chief symptom being high blood pressure, with headache and vertigo, he recalled and gave me a very accurate account of his having suffered "some sort of a venereal lesion", now clearly remembered. He was, at the time, working with a railroad bridge crew in Tennessee. Pay-day came around. Together with other members of the crew, all older than himself, he journeyed to Nashville for the week-end, and there, having illicit intercourse, suffered an infection which quite incapacitated him for some time. The facts were recited, just as I now re-enumerate them for you. It was necessary for him to temporarily give up his position. An older brother was sent for, who took him back to his home in Pennsylvania, where he had a "thorough course" of treatment with "mercury and potash". Could a faulty history be made more positive than by a recital of such facts, and yet the memory tablet was at first entirely lacking?

Then, there are the patients who, in order to tell the doctor all that he desires to know and should know, would require the unbosoming of the most sacred recesses of their souls. How often do we meet with these patients and how difficult is it to get the facts! It would be easy for any physician to recall innumerable instances, illustrative of cases of this sort. One or two more should not be amiss, ere we leave the important department of History Taking.

A young miss, age 16, was brought to us from the mountains of Eastern Kentucky. A beautiful brunette lassie. She was suffering from a very acute nephritis, which had suddenly arisen some four weeks previously. I do not recall having seen a more pronounced clinical picture: Edema, amounting to general anasarca, pyrexia, furred tongue, nausea, with persistent vomiting, anorexia, complete. Examination revealed: Rapid heart with some hypertrophy of the left ventricle, albumin, four plus, with hyaline, finely and coarsely granular casts, and with a low urea output. She presented a retinitis albuminurica. The nervous system showed such evidence of intoxication as to make us fear uremic convulsions. The past history revealed nothing that would justify the faintest reason for the condition. She had visited, beginning some six months previous, in the South and was supposed to have become infected with the malarial parasite. A letter to us from her physician was to the effect that she had been treated by him for such a condition and that the kidney state was secondary to the plasmodium. The blood failed to disclose the Laveran organism. Ours, however, was the first blood examination which had been made. The patient had simply been treated symptomatically for malaria, because she had recently resided in the malarial zone. What was really the matter with this child? Simple enough, though tragic. She was pregnant. She *knew* what was her trouble, but was unable to disclose it. I shall never forget the tragedy connected with the case—the presenting by me of the true facts to a heart-broken mother, then the later accouchement of the young mother and the finding of a home for the baby. So, I recall other instances in which, when the patient had disclosed the secret of his soul and unbosomed himself to his doctor, the diagnosis was immediate and the treatment quickly effectual.

Genito-Urinary History. Too much emphasis cannot possibly be laid upon the obtaining of an accurate genito-urinary history. We must not lose sight of the fact that venereal infections often occur at a time in life when little attention is paid by individual to self. Furthermore, we must not lose sight of the fact that men have been taught to believe that venereal lesions are of little consequence, therefore they forget such infections. It has been said that the civilized world is rapidly becoming syphilized. Let us therefore inquire searchingly of the sexual life of our patients.

Family History. More and more, we come to discover the importance of giving consideration to the family history: Age of father and mother, their previous health, if living; otherwise the cause of death of parents as well as the state of their health during life. The number of brothers and sisters living, their state of health. The number dead, the cause of death of each, with an accurate account of their previous health. We do not go amiss when we make even further inquiry into the health of the grandparents on either side, as well as the health of uncles and aunts.

Heredity. Under this caption, we have in mind chiefly nervous and mental diseases, though we also give consideration to malignancy, tuberculosis and nephritis.

Place of Abode. In the taking of the patient's history, it is interesting to know not only where the patient lives at the present time, giving due consideration to certain localities, as being more

salubrious and affording more healthful surroundings than others, but it is also proper and very important to learn *where* the patient has previously resided and for how long a period of time. In these days, when a successful warfare has been waged against the malaria bearing mosquito and against the typhoid germ, we at once realize the importance of knowing whether the individual who seeks our aid has been in the swamps of Mississippi or Alabama or has lately been in the outlying country district, where he, perchance, partook of typhoid infected water. Not infrequently does the latter infection come about, now that the motor car has become ubiquitous. Following Sunday afternoon drives into the adjoining country, and week-ends spent with the family at some resort, not infrequently the germ of Eberth finds lodgement and grows.

Marital History. In the clinic, we have frequently found it of primary importance to get a complete marital history. This should include not only the present marriage, but previous marriages, if any. Now that the divorce courts make it so easy to obtain release from connubial dissatisfaction, it is not infrequent that the patient has had previous "encounters". We want to know the health of the mate, the number and health of the children, miscarriages, if any, and how many. Recently, a male patient had difficulty in understanding why we were so persistent in knowing about his wife. We even like to know and strive to discover the family relations, as to whether they are pleasant or unpleasant. Many a man is sick and suffers from the intoxication of overwork and worry whose wife and daughters spend more than he can make. Many a man is ill on account of business reverses, which may be wholly beyond his control and fault, or which may be the result of his inattention. Many a woman is sick because of a faithless husband, and many a mother is sick because of a wayward son or daughter.

The occasion will not permit of the devoting of more time to the consideration of history taking. May I say that it has been my experience, throughout more than twenty-five years of activity in medicine, where diagnosis was uppermost in my mind, that the carefully taken history more frequently makes the diagnosis than does the carefully made physical examination. In the practice of Group Medicine, which has occupied us now more than four years, we can corroborate the observation of other groups, that the history is of paramount importance.

General Physical. By the general physical examination is understood, first, a careful inspection of the patient. This includes his height, weight, posture, gait, type, general appearance, nourishment, his mentality. We examine the skin, the hair, the nails, the glandular system, the muscular system, the osseous system, the joints and the nervous system. The examiner notes in detail any deviation from the normal which he finds, to be further studied by the special examiner. For the General Physical, the patient is stripped to the skin and examined in the sitting, standing and recumbent postures. The examiner accurately describes abnormalities and deformities, wherever they are found. The patient is carefully questioned as to all accidents and injuries which may have been suffered during his lifetime, including shocks, if any, to his nervous system. Previous operations are described, when and by whom done. As a rule, few patients know much regarding the surgical procedures they have endured. And strange as it may seem, they usually know less about major surgical operations than about minor pieces of work.

Special Physical Examinations. We divide the Special Physical into (1) a carefully made physical of the head and neck; (2) a carefully made physical of the (a) upper extremities and (b) the lower extremities; (3) a carefully made physical of the thorax; (4) a carefully made physical of the abdomen; (5) a carefully made physical of the pelvis and (6) of the rectum.

Physical of the Thorax. This includes the heart, the lungs, the mediastinum. In the making of the physical of the thorax, we include a careful survey of the entire vascular system. The thyroid gland is examined, noting any variation in size and whether the function of the gland is normal.

Physical of the Abdomen. The examination of the abdomen is done by several members of the staff. It is first done by the medical side of the staff. Thereafter, the digestive tube is emptied by a laxative or by enema or both, and the examination repeated by other members of the staff, including the surgical side of the house. Because the surgeon more frequently sees the interior of the abdomen (unless the internist has similarly had a large experience, ante and post mortem), more weight is usually attached to his findings. In our opinon, there is no basis for such a view. In the making of the abdominal examination is included a report of the condition of the rectum, the anus and of the sphincter. A report is also made of the kidneys, stating whether both organs are palpable.

Genito-Urinary Examination. The Department of Urology and Genito-Urinary Diseases makes this examination. It includes a survey of the external genitals, an examination of the urethra, together with the use of the cystoscope. In the male, the prostate gland and seminal vesicles are interrogated. Smears are obtained and cultures made, where required. In the female,

the Genito-Urinary Department makes its investigation after the Department of Gynecology has first made its examination.

Pelvic Examination. This examination includes the vagina, meatus, perineum, the uterus and adnexa.

SPECIAL EXAMINATIONS — *Dentistry.* The Dental Department makes a report of the condition of the mouth and teeth. Such teeth are subjected to x-ray as the Department of Dentistry designates. The Dental X-Ray Department is separate and apart from the General X-Ray Department, being under the supervision of the dental member of the staff. This department not infrequently *clears up* a difficult diagnosis and occasionally makes the diagnosis *in toto.*

Eye, Ear, Nose and Throat. The Department of Eye, Ear, Nose and Throat makes a scrutinizing examination of each patient, very frequently throwing such light on the case as to make the final interpretation and the general "sum up" much easier.

Orthopedics. Each patient is subjected to an examination by the Department of Orthopedics. Recently, we were wonderfully repaid by the findings reported by our Dr. Pirtle. A gentleman, age 41, had been suffering, at times, indifferent pains with more or less general discomfort all the time. He had been given sundry and diverse prescriptions, without benefit. The Orthopedic Department discovered a shortening in one leg, amounting to three-fourths of an inch, which resulted from an injury to the spine and pelvis, suffered in a railroad accident, fifteen years before. The patient had previously omitted telling us anything about this serious injury, which was the whole cause of his present ailment. X-ray disclosed the exact damage, long since crudely repaired by Nature. Adding three-fourths of an inch to the inner sole and outer sole of the patient's shoe, all of his pain and discomfort disappeared.

The Laboratories. Every patient who passes through our clinic receives a certain amount of Routine Laboratory Work—

(1) Urine:—This includes not less than three examinations of the urine, often four or more, both chemically and microscopically. At least one twenty-four hour specimen is included. A Kidney Function Test is regularly done on all patients whose urine shows marked deviations from the normal.

(2) Blood:—A blood examination is done on every patient. This includes hemoglobin estimation, red blood count, white blood count, differential count, together with a search for pathological cells and parasites.

(3) Wassermann:—A routine Wassermann is done on every patient. This is a Blood Wassermann.

(4) Spinal Wassermanns are not frequently done.

(5) Basal Metabolism is undertaken, wherever indicated.

(6) Blood Chemistry similarly is carried out, when indicated.

(7) Sputum examinations,

(8) Gastric analyses, and

(9) Feces examinations are frequently done.

(10) Goetsch and other tests are done, whenever indicated.

Roentgen Rays:—X-ray is routinely done on every patient. This includes fluoroscopy and plates of the chest, usually stereoscopic plates. A gastro-intestinal examination with the x-ray is also done, using the fluoroscope from mouth, through to anus. Plates are exposed, where indicated. Where the history or the physical examination makes the suggestion, x-ray examination is made of (1) the head, in particular of the sinuses, (2) the gall bladder region, (3) the urinary tract.

A very natural question arises in the minds of gentlemen who are not familiar with Group Medicine and Group Diagnosis. I shall anticipate this question today. Men wonder not as to the need of such scrutinizing survey of patients, but they wonder as to the Method of Management of Group Practice. It may not be amiss for me to say that the making of such an examination contemplates a large staff of men and women, and certainly a large equipment. If the group is to succeed it must be composed of individuals of large practical experience, its members having been well grounded in the science and art of medicine. Of absolute necessity and of primary importance to success is a Chief of Staff, who directs the enterprise and who carries the major responsibility. It has been said that "Every successful Institution is the Lengthened Shadow of a Single Man". Nowhere is this more certainly true than in Group Medicine.

Group Diagnosis affords its devotees a satisfaction that can only be understood by those who have access to it. A group should be located in close proximity to every city of any size. The members of the group will benefit largely by their association. The profession, whom they assist, and the public, whom the Group serves, will benefit even more. Modern day diagnosis is the more accurate in proportion as the Group undertaking the diagnosis is composed of men specially trained for the more especial work.

THE PHYSICIAN

DUTY TOWARD THE PSYCHOLOGICAL DEVELOPMENT OF CHILDHOOD AND YOUTH IN THE HOME*

FRANK B. WYNN
INDIANAPOLIS, INDIANA

Of the various organic systems of the body, Nature points out that which is most important. The bony skull and spinal column indicate the precious nature of the contained structures—the brain and spinal cord. With other organic systems medicine has made tremendous strides toward conserving integrity. In the case of the gastro-intestinal tract elaborate sanitary measures have been established to protect against contaminated water or food-stuffs. Carefully wrought-out instructions have been devised concerning the danger of lung injury by the inhalation of infectious, physical or chemical substances. Much has been written about the tonsils and teeth as portals of entry of pathogenic organisms to the body. But what has been done to guard the central nervous system from mal-development or to foster normal development of this, the presiding and supervising genius of all our functions?

Man as a sentient and thinking being is such because of his central nervous system. Its proper functioning underlies efficiency, attainment, contentment. Who will contend that the growth and powers of the central nervous system are not influenced by heredity, environment or training; or deny that its capacities may be retarded by accidents, obstacles and rebuffs? Conversely all acknowledge that its growth and stability are favored by good mental hygiene, methods which bring encouragement, achievement and establish the habit of nervous stability. During the moulding period of childhood and youth, good training will make, just as bad supervision and direction will mar, the capacities for mental and moral achievement. How great therefore the responsibility of those charged with the rearing and education of children.

To those on whom this privilege and task falls, it should be the duty of the physician to make plain the nature and seriousness of habit formation. First let it be made clear that acts often repeated become second nature, the nerve-center reactions and impulses causing structural changes, which persist just as do scars from injury.

Many of the body acts are at first instinctive but later become from repetition habitual; as the taking of food. Other acts require at first the exercise of reason but later are performed automatically without the use of the higher intellectual faculties. A pianist, for example, reads a difficult composition. In the learning this is an intellectual process. The piece is played over and over again until memorized. Now the composition is rendered without detailed mental effort, the fingers performing the intricate movements more perfectly than was at first possible under mental concentration. The procedure is a complex finger movement which the sub-conscious and reflex centers execute with amazing celerity and skill. In like manner writing, walking and talking are at first mainly intellectual procedures but with endless repetition, the subordinate centers take over the performance. The same principle of sub-conscious and automatic control underlies all manual pursuits. Habit formation, then, is at the bottom of both the artistic and useful accomplishments in life. All have a physical basis in the central nervous system and when once well learned one may properly say that a record has been made and preserved in the sub-conscious realm of the nervous system. Once in a while when desired the intellect, through the memory, pulls out a record but the sub-conscious and automatic centers must be depended upon to reproduce the details, e. g., piano playing, skating.

Just as good habits are acquired by proper training, so do bad ones arise from improper methods. When Shakespeare wrote, "How use doth breed a habit in a man," he had in mind the unfortunate results of bad moral training. Acts at first consciously wrong, repeated over and over, lose the pangs of guilt, coming gradually under the control of the half-conscious centers which in time dominate even the intellect and the will. The individual becomes the dupe and slave of his brute impulses. For example, violation again and again of the seventh commandment leads ultimately to supremacy of the sexual instincts over the intellectual and moral centers, resulting in a prostitute—male or female. Habit channels are worn deep, producing structural alterations not likely to be righted, or at best most difficult to change. Is the prostitute or the confirmed drunkard easily reformed? No, because permanent structural damage has been done to nervous tissues. Does not the same physiological law hold good with regard to other immoral habits as well as mental and temperamental faults of adult life? One of advanced maturity only needs to consult his own observations and acquaintanceship with people to support the contention made. Have you not known children of violent and uncontrolled tempers who became naturally, almost inevitably, irascible and unreasonable men? Have you often observed indolence and slothfulness in a boy followed by industry and orderliness in the man? Cynicism, pessimism,

*Twentieth of a series of articles by Dr. Wynn which are appearing regularly in THE JOURNAL.

selfishness, whining, faultfinding, lying, carelessness, slovenliness, when found in the adult are dominant characteristics which might, by proper training during the moulding period, have been prevented or greatly modified. Uncorrected in childhood and youth they become habitual handicaps. As with Cain of old, they stamp the individual with the mark of inefficiency throughout life. Whilst the test-tube and microscope may not have demonstrated the existence of tissue changes in these cases, as observant physicians are we not convinced that acts long repeated during the moulding period of life, eventuate in physical changes in the nervous system as real and difficult to efface as a scar upon the arm?

The more general acceptance of the seriousness of these truths should impress upon the world the extreme importance of correct training during the growing period of life. The music master does not hope to develop a great violinist without patient and painstaking instruction of the pupil in childhood. The building of good character or stable temperament, by wise and tactful control in childhood, is just as important as the making of a good musician.

The prevention of bad habits and the cultivation by proper training of good ones is the greatest mission of parents. Correct habit-building should be the chief purpose of education. That the present age falls short of duty and opportunity is often apparent in the home where the responsibilities of motherhood are put aside for the glare and whirl of social life; or in the case of the father, in whom the place of parental comradeship with sons is usurped by commercial or professional ambition. And in schools and colleges the disposition is to cram the brain with mere knowledge rather than to build well the foundation for character and self-mastery. Many parents unfortunately entertain the false view that childhood is a complexus of carnal impulses which in the course of time will burn out and leave the organism unharmed. As well might the farmer say, "Let the weeds grow, the corn will take care of itself." Without discipline, tactful but firm, there can be no schooling in self-control, and a bad foundation is laid for habit handicap later in life. The parent who draws back from the correction of a child, kindly but firmly, is not generous but selfish. Too often the world indulges in a sort of maudlin glorification of the mother who indulges her children excessively, excusing it on the ground of her supposed love for them. The fact is, she is coddling her own selfishness; sparing her own feelings of present discomfort. The higher and truer form of love for her offspring would look to the future of the child, and be willing to make sacrifice of feeling now for the later good which would bless the life. Any other course is short-sighted—often it means the sowing of seed which will reap a whirlwind of misfortunes in later life.

The writer accounts himself unusually fortunate in having had parents unafraid of duty in these respects. My father, extremely devoted to his children, had a far-seeing mind and an acute conscience which took in our lives as totalities—the present and future potentialities for good and evil. In every parental emergency, the query submitted to his conscience was, "What is best not merely now but for the full rounding out of my child's life?" With quick decision he saw and executed, kindly but unwaveringly. A personal illustration does not make the example less instructive.

The writer, like all healthy country lads, had a voracious appetite for the good things of the table, often to my later distress. With sound reasoning father placed a ban on these excesses. When occasion arose for the possibility of appetite abuse, the law was applied, whereupon I protested in fury and created a "scene". Without more words than that one helping was enough, he called for the "cold towel". This was wrung out of ice-water, then applied over my face and neck, causing several deep inspirations and the cooling of my wrath. With every impassioned outburst this was repeated. On his part there was no anger—no quibbling or argument. Whether at the table or elsewhere, any of my emotional explosions were treated in the same manner—always with a calming and satisfactory result. A few months of this treatment established my self-control.

Of the definitely recognized, functional, nervous disorders which arise during childhood or adolescence, hysteria is perhaps the most frequent. Whatever the hereditary background or individual predisposition, it is universally recognized that mental and moral factors bring on the storm—the loss of inhibition followed by an overwhelming flood of emotions. These tremendous reactions must of themselves produce marked changes in the nervous centers. A few such explosions and the "hysterical habit" is established for life. A trifling assault only is necessary to knock down the floodgates of inhibition, and away goes the maddening stream, sweeping reason and judgment before it. Knowing these things to be true, should we as practitioners, not more frequently seek to anticipate and prevent the growth of the "hysterical habit"? Let a general practitioner, in whose office the writer was a student, speak in his matchless way upon this subject.

In the practice of Dr. S. was a family of high social position and ample means. The parents were over-indulgent to their two sons and a daughter just budding into womanhood—a

beautiful girl whose every whim was gratified. She lay abed in the morning late, often eating breakfast in her room. No household duties were required, certainly no drudgeries or tasks which called for patience and personal sacrifice. There grew up in her mind the idea that nothing she was called upon to do should be hard or disagreeable. Her mother was always cautioning her against anything that would make her tired—mentally or physically—as though it were a sin to exercise brain or muscle to the point of fatigue. Thus coddled from year to year a superior product of inefficiency resulted. It was easy to predict what would happen later in high school and college. The hard subjects were shied at or side-tracked for easy elective courses which did not require so much effort. Even then examinations often brought failures which maternal sympathy protested against. There were lapsed hours and days, with feeble excuses of headaches, calling for a doctor's certificate, which he always made out with a wry face. Social functions were entered into with zest until things went counter to her pleasure; then ensued a nervous explosion. Was it the failure of her lover to take her to some coveted entertainment, or a quarrel with someone in her "set",—up went her anger in uncontrollable emotion and down her spirits to the depths of prolonged despair. These tantrums were becoming more frequent and the doctor felt called upon to do more than prescribe valarian and bromids. He asked a conference of the parents and daughter in his private consultation room. Seating them he began, whilst I (by his suggestion) eaves-dropped from the little drug room in the rear. "As memory recalls," he began, "it is about twenty-five years since I came into your lives. It has been a fine relationship, more precious to me in the mutual confidence and friendship enjoyed than in the material rewards. John, I have seen you and Mary through some pretty tight places, and now you are in another. It is a most delicate matter that I want to discuss with you, and the expression of my opinions may cost me your friendship, but I shall at least enjoy the consciousness of having done my professional duty. In order to avoid an unseemly quarrel at this time, I am going to ask you to keep still until I have finished. Then let us see if we cannot shake hands and start in with unwavering determination to win this battle. Now while Helen is the subject of our anxiety at this time, I want to say that I honestly think that her parents have been more to blame than she has been. You have allowed her instinctive impulses to have sway until they have become habitual, dominating the finer traits of character. You are making out of her a physical, mental and moral "tenderfoot"—no physical endurance developed, no intellectual tenacity cultivated, no moral stamina and self-control to balance, co-ordinate and carry through the problems of life. For this neglect she is reaping the penalty in these nervous explosions. It is developing into a plain case of chronic hysteria. But don't flatter yourselves that hysteria is any simple malady which can be readily cured or thrown off at will. The thought of smallpox or typhoid fever strikes terror to your souls, but as a physician I say to you that chronic hysteria is infinitely worse. Helen, these paroxysms if not checked in due season, will continue throughout life, interfering with domestic responsibilities, child-bearing and child-rearing. Your hygienic, physiologic and psychologic training along right lines just now is vastly more important than a college diploma, any social prestige you may acquire, or any dowry your parents may bestow. Furthermore, is it quite fair to the splendid young man who is a suitor for your hand, that he should not know the exact nature of the attacks you are having?

"Helen, it is worth remembering that I helped celebrate your first birthday, and gave you your first spanking. And now I am giving you a mental flogging that will do you more good than the first one. The truth is, I think you so fine that I want to see how good a job I can make out of you. You have been a sort of frisky colt, frolicking around in rich pastures, kicking up your heels and doing just as you pleased. Now you have reached the age where you must get into harness and pull loads—that is the order of life if we live up to duty. The folks have not held the lines very tight. Consequently you went your own gait, balking now and then or kicking off the harness (always a serious thing in the breaking of a colt) and now they are turning the lines over to me. So it is for me to teach you how to pull the load.

"These are most serious problems for you, my dear child, which, as a real friend and a good doctor I want to help you solve in the right way. The first medicine I prescribe is to be taken before breakfast—an hour's walk, rain or shine, summer or winter. No leniency is to be shown in this matter without my consent. Secondly, the minute you find from any cause those terrible impulses seizing you to kick off the harness, make a bee-line for my office. I'll mount 'Old Bill' and you can ride Fanny—the finest saddle horse in Indiana. We'll gallop away to the country. While I minister words of encouragement and remedies to alleviate the suffering of poor old Mrs. Armstrong, dying of cancer, you can sit on the creek-bank under the trees, and profit by their wise counsel. Their leaves will whisper to you 'Patience! Patience!' They will tell you about the tedious hundred years they have been steadfastly at the job the Creator gave them to do. They will pour out the soothing balm of meditation on your fretted

nerves. Their quiet dignity and tender ministrations will build anew your hope and renew your courage to fight a good fight. O! Yes, Helen, you are going to win this battle! You have from fine parents the mettle in you to do it. All that's necessary is to get it to working properly. Your General commands. Attention! Forward march!" Then with pretended military pomp he strode over to her chair, took her shapely hand between his big ones and let out one of his rollicking laughs. He had won. No debate of the question was necessary. "Yes, doctor," said Helen, "I'll follow where you lead." And she did. Mutually faithful, doctor and patient labored years in the rebuilding of her temperamental impulses. She developed along wholesome physiologic lines into a wonderful woman. Who can measure the material price of the service this prince of physicians rendered? Compare his psychic and spiritual artistry with the mechanical technique of the operating room. Which shines with the greater luster?

Parents need instruction in the physiology and psychology of child-control and direction. They should be taught the methods most likely to attain results. Instead of parental neglect in training as illustrated by the latter example, one sees just as often the precise opposite, a nagging discipline, which is worse than no training. What is here said of parents is equally true of teachers, superintendents, the heads of great commercial and industrial concerns, managers, foremen and the like. From childhood to old age there are arising constantly these psychological and ethical problems which have more to do than aught else with efficiency and contentment in life. Is education doing all that it should in this direction? And finally may it not be contended with reason that our profession should be the leaders to show the physiologic highways along which to travel?

THE DANGERS AND DUTIES OF THE HOUR*

HOBART A. HARE, M.D., LL.D.
Philadelphia, Pa.
Professor of Therapeutics and Diagnosis in the Jefferson Medical College

The title of my address is taken from one by Dr. William Goodell, a graduate of Jefferson College, but who was for many years a professor in the University of Pennsylvania. It was entitled the "Dangers and Duties of the Hour." These today are so varied that it is impossible for me, in the few minutes that I can detain you, to take all of them into consideration; but I shall speak of a few of them.

*Address delivered at the banquet of the Medical Society of New Jersey's Annual Meeting at Atlantic City, June 15, 1921. Reprinted from Journal of the Medical Society of New Jersey, December, 1921.

As we all know, there is a curious condition of unrest and lack of solidarity in the world at present. There is an existent idea that all men should get something but give nothing for it. Some men have the belief that they were born into this world to reform everybody else with the idea of standardizing everything we touch and do. Our food is standardized; our drugs are standardized; our forms of medical practice are standardized. They say we shall do this or that. They standardize our hospitals, whether in a town of five thousand, or in a city of two million inhabitants. They are saying to free-born American citizens, "If you are going to be in Class A, you must do what we say, and if you do not do what we say we will publish your name as belonging to Class B." Often you find that the instigators of these measures belong to one of two classes; they are either men who have not made a success of practice and are running off on some side line which they are free to follow, or because of some fault in their mental structure, so to speak, they go about devoting themselves to the task of trying to direct their successful brethren. They have wild ideas, and decide that the rest of the medical profession must be guided by what they say.

Long-haired men and short-haired women go to Washington and lobby. They buttonhole Senators and Representatives, and make them believe that there is a real demand for what they ask; and the Senators and Representatives pass a law to get rid of them. As a celebrated politician said, when I protested against a certain law being put through, "You do not know much about these things." I said, "I do not; but what I do know, I hate like the devil." He said, "This bill is going through, and will be signed, but the amount of money that will be appropriated to enforce it will be so small that it will not amount to anything. That will get rid of the long-haired men and short-haired women; if we do not think the bill is a good one, we do not make a large enough appropriation to enforce it," but a real danger exists, for these people are now attempting to tell us how to live while we are trying to make our living.

We find members of our profession, with great enthusiasm, many of them conscientiously believing in the correctness of their views, advocating propositions by which medical men will become mere hacks by reason of laws supposed to help the people. If we do not look out we will fall into the position of the panel doctor of Great Britain. I heard the story of a poor panel doctor in London who is paid less than one of their bus drivers. In writing a prescription for one of his poor patients, he ordered twelve capsules, but the patient took only

eight. What do you think happened? A couple of politicians that controlled that particular district called the poor fellow up before them, criticised him, tried him and finally fined him because he had put the city to the expense of putting up four capsules more than the patient needed. The men who did this were commonly known as "Bath House John" and "Hinkey Dink."

When the medical profession permits itself to resort to health centers and poor law clinics, it is being euchred out of its own. It is deceived by a star, which is going out as soon as its members try to grasp it. Group practice, which is a much more ethical procedure, is dangerous. Some of those who know the results of group practice describe it in this way: A man forms a "group" which begins to touch the borderline of non-ethics, because they are going to work as a bunch and get all the business or trade that they can, each for the other. After this has been going on for a while, the man who formed the group, and considers himself the head of it, finds that a large part of the patients are going to one of the other members of the group, because they like him better than himself. Jealousy is aroused in the group and the group falls apart. One man says that he was inadequately paid; another has failed to get his percentage; and the fourth says that the first man hogged the whole thing.

Is there anything in the practice of medicine carried on in that way? No. Practice must depend on what the man is himself. There cannot be a department store arrangement in the practice of medicine, because it is a profession and not a business. In the former you are dealing with the sick who depend on you to be human and humane, but in business the principle is *caveat emptor,* let the buyer beware.

There are other things closely related to the practice of medicine and to the great economic problems, such as the Pure Food and the Drug Act. Under the Harrison Act, they have no right to tax us three dollars a year, so they call it a license. In other words, a legitimate practitioner is taxed because he uses morphine, or other pain removing drug, for a patient who is in agony. Why not fine the life-saving squad each time it brings a man ashore? They do not use the dollars they collect for the uplift of the profession, nor do they use three hundred thousand dollars or more for the benefit of people who failed to get the morphine when they needed it. On the contrary, it is not spent for anything that has any connection with the medical profession or suffering humanity. It is a gouge, and should not be permitted. It is our fault that this is permitted.

Some of us say, "No one is interfering with us;" then suddenly we wake up and find this Harrison Act or the Volstead Act is jammed down our throat. This happens to you and it happens to me. When I wanted to get a license so that I might prescribe some whiskey for a dear old lady of ninety, on whom it acts better than anything else in smoothing the rough path of old age, I was handed a blank to fill out and told I must state whether I was an allopath or a homeopath, I said, "I am neither." The clerk said, "You must be one or the other." I said, "I am a regular practitioner of medicine. I will do anything for anybody that I think will do any good. Why should I be called an allopath? He said, "If you are a homeopath, you get a permit for sixteen gallons; but if you are an allopath, you get a permit for only three." It looks as if the homeopaths had been able to convince the authorities at Washington that like cures like, but the prohibition officer said that they use the alcohol to make their tinctures.

Where are we, that because a man chooses to call himself a homeopath, he can get sixteen gallons, and because he calls himself a regular practitioner, he is limited to three gallons? Is this a free country, under these circumstances? I think not. This is because we neglect the dangers and duties of the hour.

There is a large Chiropractic College in Iowa which graduates more chiropractors in a year than all the medical schools in the United States graduate regular physicians in a year. The other day a man, a supervisor, said that he had a boy that he thought would like to study medicine. He did not know anything about medicine. That is the trouble with the laity. They do not know anything about medicines. If you give them an ointment and it cures them, they think you are a great doctor but if you talk to them of a polymorphonuclear count, they do not know what you mean. This man made this cold-blooded proposition: He said, "I am a man with a large family, and cannot afford to spend much money for the education of my boy. I have been looking into the matter and find that if he studies medicine, it will be five or six years before he earns a dollar; but if he goes to a chiropractic place, he will make money in a year or eighteen months." It was true. There was no use in arguing with him, or saying, "You ignorant fool; your boy is probably of the same character as you, and ought to be a chiropractor."

I recently visited a town not far from here, where there was a grocery store on one corner, and a store of another kind catacornered from it. These stores were the homes of two boys who had wanted to study medicine. One boy

spent four years studying before he graduated. The other became an osteopath, and was practicing for four years before the other boy came back with his sheepskin and from his hospital service. From the standpoint of fathers, the one who became an osteopath and an early money-maker did the wisest thing. You cannot correct this view by defamation or making fun of it. You can correct it only by an educational campaign.

Now, as to the best means of opposing this danger to the people rather than to ourselves: It is not by going to the Legislature and fighting it on the ground that it is some form of irregular practice. The best method is to educate the laity, so that they will recognize that these various peculiar cults and schools never do anything except for one purpose, as has been illustrated on this stage tonight. The laity do not know that almost every man in the medical profession of the United States does fifty percent of his work for nothing, as I happen to know from the investigations that I have made. The way to combat quackery is not as two camps engaged in commercial pursuits would try to correct it, but by a process of education.

Not long ago I had an amusing experience, when a patient of mine went to the altar of a foreign god. She told me that she had been under the care of a certain osteopath, and said, "I hope you do not mind." I said, "No; the more he practices, the more I get." "Isn't that funny," she remarked, "that is just what he said about you!" I mention this joke on me because it illustrates the fact that you cannot do anything in the way of opposition except by education. A bank president in Philadelphia was told by a quack that he could cure him of cataract by reducing a dislocated spine. He does not know medicine, although he knows law. He should have enough education to know that he could not be cured of cataract without a surgical procedure. He must be educated, so that he will not be fooled.

I have been rather diffuse in my remarks tonight; but I told you when I began that the topic was a large one to cover. After all, what does this topic mean? It means that the dangers and duties of the hour require that the New Jersey State Medical Society, and every other State Medical Society, should do as this Society has done: Charge as a phalanx, and fight not only against the outsiders, but also against the small group inside.

In my opinion, the present organization of the American Medical Association has certain serious objections. In the old days, when there was a meeting, all of the men coming from a certain State got together and acted as a group representing that State, to put through such legislation for that State or the country as seemed wise. When the association got larger, it was decided that there must be a House of Delegates, and a comparatively few rule this, when you consider the number of men represented. The State of Pennsylvania has only six or seven delegates; the State of New York, nine; the State of New Jersey, three. This House of Delegates meets, and what is it made up of? It is made up always, of course, of men who are worthy members of the medical profession; but they are not usually chosen as members of the House of Delegates because they know anything about the business that is going to be transacted. On the contrary, the State Society appoints them as delegates because they are good fellows, because they are going to the meeting any way, or for some other reason. They go to the American Medical Association meeting, and do not know anything about the business to be transacted or the problems to be discussed, and somebody gets up and says that the Council on So-and-So recommends the adoption of the following resolution—perhaps that alcohol is never of value as a drug, and is always harmful (which is ridiculous, because it is untrue and it is no more deleterious than any other drug). "All in favor of this resolution, please say 'Aye'" and Dr. Jones of Rural Lake and Dr. Smith of Tunk Town shout "Aye", and it is telegraphed all over the land that the American Medical Association has passed this resolution, and that thousands of the medical profession assert as a body that alcohol is always a poison, and never of value as a drug. The newspaper does not say that a large minority voted against this resolution, or that a small majority voted for it, but it goes out as a statement of the whole medical profession, although the section made up of pharmacologists who devote their lives to the study of the action of drugs protested against such action being taken.

What then are we to do? We must at one and the same time preserve the rights of the individual and maintain the rights of the profession as a mass. While we are busy with the sick we must remember that there are others who are busy with our affairs and should be watched. There is too much influence exercised by an active small minority and too little by an inert great majority. The latter must be more active in asserting their beliefs and wishes.

GROWING OLD GRACEFULLY

It often has been said that few medical men grow old gracefully. So many of them who have been honored by their confreres and been eminently successful in public estimation begin to show peevishness, ill-concealed jealousy, and oftentimes an all-around crabid disposition after they pass middle life but are still young enough and active enough to continue in practice. Probably this is due to what is commonly termed "slipping", and a realization that reputation and skill are not held in the same esteem as formerly by either confreres or public. Some doctors who have enjoyed a large and lucrative practice sour on the world when they discover that the volume of professional work is diminishing and patients are deserting them for younger if not more competent confreres. One may be only "as old as he feels", but there is something about the practice of medicine which makes length of service count in the appreciation of confreres as well as public in the estimation of efficiency, and whether we like it or not, or whether it is just or not, the tendency on the part of many people is to count age and length of service after a certain length of time as increasingly depreciative of efficient professional service. This is more apt to be true in those too frequent instances where the successful practitioner gets independent and perhaps tactless with advancing years and increase of reputation and practice. It really is unfortunate that so many medical men feel that they should be able to do as much and as good work in the twilight of life as they did in their prime, and it is really pathetic to see them evidence their dissatisfaction with progress of age and its attending limitations of efficiency. It is perfectly natural that the younger men should step into the shoes of the older men, and there is every reason in the world why the older men should be willing to have them do so and without any sense of regret, jealousy or antagonism. To grow old gracefully may be a difficult problem for many of us to solve, but it is worthy of serious consideration if we expect to hold the love, respect and appreciation which has been accorded us in the prime of life.

MEDICAL VERSUS LEGAL CHARITY

We have heard recently of an incident which shows the difference between medical and legal men when it comes to the exhibition of charity. A poor woman having little to keep body and soul together suffered an injury for which she received a total compensation of one thousand dollars. The physician who took care of her for the injury was asked by her attorney for a bill and the physician replied that inasmuch as the poor woman had nothing, and whatever she received as compensation would be no more than needed to support her, he would donate his services. To this the lawyer replied that there was no reason why a bill for medical and surgical services should not be rendered inasmuch as his client was receiving one thousand dollars in cash. The lawyer further volunteered the information that inasmuch as the legal bill was four hundred dollars there was no reason why the doctor should not be paid; to which the doctor answered, "Certainly if you are going to take four hundred dollars from this poor woman for the small service that you rendered I haven't the nerve to charge a cent for my services, even though I consider my services much more valuable than yours in this particular case."

Incidents of this character could be multiplied many fold. Some lawyers may be charitable in dealing with their poor clients, but such incidents are few and far between. Furthermore, when it comes to a question of fees, the lawyers have the doctors beaten a mile. A lawyer doesn't hesitate to charge anything from five hundred to twenty-five thousand dollars for writing a will for a man who is only comfortably well off, when the real work of writing the will is turned over to a salaried clerk and no particular skill on the part of the lawyer is exercised. Likewise, in defending a man in a civil suit the fee oftentimes is exorbitant, and yet whoever heard of any complaint on the part of fellow lawyers or for that matter how often does the client offer any objections? For defending a man in a criminal suit, the sky is the limit in estimating legal fees, and no hesitancy or qualms of conscience interfere with the assessment of a legal fee that perhaps takes all or nearly all that the luckless victim possesses. In comparison, if a doctor charges a mere pittance for saving a human life perhaps a howl goes up from the patient and is reiterated by some attorney who never misses an opportunity of gouging his clients. When it comes to legislation, did you ever hear of any legislation that was inimical to the interests of the legal profession? One reason for this is that many lawyers engage in politics and occupy positions in our legislative halls, but another pertinent reason is that, unlike doctors, the lawyers "stick together".

The lesson from this is that doctors should not only "stick together" but should use their voices and influence in making the public appreciate their services in dollars and cents value. Free clinics, dispensaries, and now the new uplift schemes for getting skilled medical and surgical services to the masses at nominal expense, are the factors that depreciate the value of the medical man's services. By all means let us continue our long established custom of bestowing charity when charity is due, but we should frown upon all the socialistic schemes advocated by false reformers who are proposing schemes that both pauperize the community and depreciate the value of medical services.

FIGURES NEVER LIE—BUT FIGURERS DO

Those practitioners of the healing art who maintain that all pathologic conditions, from cancer to chilblains and from soft corns to hardening of the liver, are due to subluxated vertebræ impinging on spinal nerves are republishing their annual batch of "statistics" on the chiropractic treatment of influenza. The standard advertisement runs, in part, as follows:

The Following Statistics of the 1918 "Flu" Epidemic Are Respectfully Submitted:
One of Every 16 Patients Died Under Medical Treatments.
One of Every 127 Patients Died Under Osteopathic Treatments.
One of Every 513 Patients Died Under Christian Science Treatments.
One of Every 886 Patients Died Under Chiropractic Adjustments.

These figures, of course, are evolved from the inner consciousness of those gentlemen that furnish verbal ammunition for chiropractic advertising campaigns. But, even assuming them to be correct, just what do they prove? They prove that many more people die when under the care of a physician than die when under the care of an osteopath, a Christian Science practitioner, or a chiropractor. The medical profession is perfectly willing to admit this; it is equally willing to admit that the vast majority of those who die, die in bed. Neither of these somewhat self-evident propositions, however, argues that scientific medicine is more dangerous than chiropractic, "Christian science", or osteopathy, or that a bed is a dangerous place. They do prove that most people who are sick enough to be in danger of death are usually in bed and under the care of a physician. Anyone who is familiar with the facts may admit that comparatively few people die while directly under "chiropractic adjustment", or any other of the fad "treatments". There are two outstanding reasons for this. The first is that the man who relies, for example, on chiropractic for the relief of some passing indisposition precipitately deserts this cult when he realizes that he is dangerously ill. Then he calls in a physician; should he die, he dies under "orthodox medical treatment". The second reason is that, should a patient die under "chiropractic adjustment", the law would require an inquest, as in very few states in the Union are these gentry permitted to sign death certificates. It is notorious that when the "patient" of a chiropractor becomes dangerously ill, the chiropractor urges the family to call in a physician.—*Journal of the A. M. A.*, March, 1922.

THE ST. LOUIS MEETING OF THE AMERICAN MEDICAL ASSOCIATION

The arrangements of the St. Louis profession for the meeting places for the Session of the A. M. A., which is to be held in their city May 22-26 next, are singularly fortunate and convenient; never has the Association been so well favored in this respect. The district in which the meeting is to take place is at the west edge of the business section of the city, easily accessible from all directions by street car or otherwise and not more than fifteen minutes' street car ride from the most distant hotel. The grouping of the meeting places is so compact that should one walk from the Registration Building (Moolah Temple) to the farthest hall it can be done in ten minutes or less; from section to section is a matter of from one to five minutes. The convenience of the location and arrangements of the different halls is more outstanding than in any other city in which the Association has met, and a decided improvement over the accommodations which were had at the meeting in St. Louis, 1910.

The Registration office, Post Office and Commercial Exhibit are to be in the Moolah Temple (Shrine), a beautiful and commodious building on Lindell Boulevard, two blocks west of Grand Avenue. At the other extremity of the group is the Odean, the home of the St. Louis Symphony Orchestra, with a main hall which seats better than 2,000, and several lesser halls. The main hall will be used for the opening session. Its acoustics are particularly good and suited to our purpose. The Sections on Practice of Medicine and on Diseases of Children meet here. In the assembly hall of the same building the Sections on Pharmacology and Therapeutics, and on Pathology and Physiology, will meet. (It will be noted that there has been an aim to foregather closely allied sections.) The Sheldon Memorial, a very beautiful new hall on Washington Avenue one-half block west of Grand Avenue, which most admirably meets all requirements, will be the meeting place of the Sections on Ophthalmology, and Laryngology, Otology and Rhinology. The Section on Surgery, General and Abdominal, and on Obstetrics, Gynecology and Abdominal Surgery, will be held in the Third Baptist Church on Grand Avenue, a situation well suited to the demands. The Sections on Orthopedics and Nervous and

Mental Diseases will meet in the Law School of the St. Louis University, on Lindell Avenue, a few steps west of Grand. The hall easily seats 500 and is both comfortable and convenient. Dermatology and Syphilis and Urology will use the large Union Methodist Church, on Delmar Avenue just west of Grand, which meets every requirement. The Sections on Gastro-Enterology, Proctology and on Preventive Medicine will use the large hall in the Musicians' Club on Pine Street, east of Grand Avenue, and next to the building of the St. Louis Medical Society, where the House of Delegates will hold its sessions. The Section on Stomatology is assigned to the assembly hall of St. Peter's Parish House, one block west of Grand on Lindell. Immediately in this district will be found three of St. Louis's most important clubs, the St. Louis, University and the Columbian. Restaurants catering to every grade of patronage are numerous in the district and precautions have been taken to insure that normal rates continue during the meeting.

The St. Louis profession is preparing for an unusual attendance; hotel reservations are coming in rapidly, but it is purposed that even the late comer shall be comfortably housed. The wise traveler, however, makes his reservation as early as he finds it possible. Dr. M. B. Clopton, 3525 Pine St., St. Louis, is Chairman of the Committee on Sections and Section Work.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

ANY physician who desires to present a paper before the Surgical Section of the Indiana State Medical Association at the Muncie session, September 27 to 29, should communicate promptly with Dr. H. W. McDonald, Newcastle, secretary of the Section.

THE little town of Stanford, Monroe county, situated in the center of a wide, unopposed territory, is without a physician, and the citizens are asking assistance in securing a good doctor for that community. Any doctor interested should address C. R. Young, Stanford, Indiana.

IT is not too early to remind those who desire to present papers at the Muncie Session of the Indiana State Medical Association that the program committee is now looking for contributions. Inasmuch as papers are divided among the three sections and the general meeting, contributors are requested to write the secretaries of the sections.

ACCORDING to the February 15 issue of the Western Christian Advocate, Christian Science quarrels are disrupting the erstwhile pacific society. The net earnings of the publishing company have fallen from a profit of $500,000 a year to a loss of $20,000 a month. *The Christian Science Monitor* has lost 80 percent of its circulation. Mrs. Eddy is no longer here to compel obedience, and so the autocratic organization breaks up.

IN the roll of honor of the United States representatives who voted *against* the Sheperd-Towner bill we can place the names of Merrill Moores, of Indianapolis, and Milton Kraus, of Peru. They deserve the thanks of the thinking element in the medical profession. These men, with the exception of William R. Wood, of Lafayette, who did not vote, are the only ones out of thirteen Indiana congressmen who did *not* vote for the Sheperd-Towner bill.

THE medical profession is honored in the appointment of one of its members to the President's Cabinet. Dr. Hubert Work, President of the American Medical Association, who has been serving as assistant postmaster general during the present administration, and has now been appointed Postmaster General, is the first physician thus honored since Dr. James McHenry served as Secretary of the War in the cabinets of Washington and Adams. Dr. Work is eminently capable of filling the position in which he has been placed.

THE Public Health and Social Welfare Committee of the Massachusetts Legislature has voted unanimously to report adversely on accepting the Sheperd-Towner law. It is expected that other states will take a similar stand, and it is not too early for the medical men of Indiana to think of having this state reject a law that is iniquitous in effect and is not at all in the interests of maternity. If adopted it means increased taxation without corresponding benefits. Its main provision is to give jobs to a lot of office parasites.

WE desire to call attention to the "Ten Commandments of Medical Ethics" formulated by Dr. Frank B. Wynn, of Indianapolis, and published in the February number of THE JOURNAL. Complying with the request of numerous friends, Dr. Wynn has had these ten commandments artistically printed in colors and handsomely illuminated by a specially designed border illustrating the history of medicine in symbols. This reproduction is suitable for framing, size seventeen by twenty-two inches, and the price, postpaid, is two dollars, which may be sent to F. E. Dillan, publisher, 817 Hume-Mansur Building, Indianapolis. These commandments are worthy of a place on the wall of any physician's office. They are a good reminder to the physician of how he should conduct himself, and they also are a good reminder to the lay person as to the aims and objects of medical practice as conducted by the honorable and ethical physician.

"Watch your step!" is an injunction which should be well considered by some of the leaders in our medical profession who intentionally or otherwise are giving their support to various uplift schemes which in the ultimate analysis mean the socializing of the practice of medicine. Free hospitals, free clinics and a dozen or more allied plans for furnishing free medical and surgical service to the public are receiving more or less support from some medical men who later on will live to regret the action, but who at the present time deserve the severest condemnation of their confreres for an action that tends to pernicious results. This whole tendency to socialize the practice of medicine has been insidiously but steadily growing during the last few years, and the pathetic feature of the matter is that much of the movement has been supported and sometimes instigated by medical men probably without thought as to the ultimate vicious results. Already a storm of disapproval is coming up from the rank and file of the medical profession, and those who intentionally or unintentionally would destroy private medical practice as it exists today will be opposed most vigorously.

THE Board of Trustees and the Judicial Council of the A. M. A. have taken notice of the open letter addressed to the County Medical Societies by a so-called "medical advisory committee" by issuing a statement in which they admit that at present there is great need of calm, deliberate consideration of how best to check cer tain dangerous tendencies affecting the practice of medicine, and to remedy serious conditions that already exist. They condemn the communication as being destructive in character, but admit the need of suggestions as to the best method of combating the evils that threaten public and professional welfare. As a matter of fact reforms are seldom brought about without calling attention to the need of such reforms. Pointing out evils that exist is not destructive, and pointing out the dangers of innovations that are proposed should not be considered a breach of propriety. In the medical profession we are too prone to let a few do the thinking for us, and those few oftentimes are too apt to take offense if either their motives or their actions are questioned. Anyway, the subjects which have brought forth discussion are worthy of serious consideration and no doubt much will be accomplished that would not be accomplished were it not for the agitation that has been started by a few men who now are not in particularly good favor in the eyes of some of those who at present rule the destinies of the American Medical Association.

THE newspapers announce that Dr. William J. Mayo, the celebrated surgeon of Rochester, Minnesota, is building a palatial combined yacht and houseboat, with facilities for entertaining numerous friends and with special arrangements for housing and unloading a sufficient number of automobiles to entertain the party when stops are made. Some newspaper writers have remarked that "it pays to practice medicine", but we can assure them that doctors who own private yachts are almost as scarce as hen's teeth. However, why shouldn't the wizards of the medical profession own yachts the same as those who are successful in other vocations? It is a little unfair to jump on medical men continuously because in rare instances they happen to acquire a little property or even put forth an effort to get what is justly due them in compensation. The reason for this is not hard to find, for from time immemorial doctors have been an easy going class, content to relieve suffering humanity with scarcely a thought of reward except that which goes with the knowledge of doing good. The Mayos have been good business men as well as good surgeons. They have exacted toll where toll was due, but, on the other hand, they probably have shown as much if not more of the milk of human kindness as the average doctor. Some of us can never obtain their present position in the financial and medical world but we are not going to criticize or be jealous because they have been more successful. We are only sorry that there are not more men in the profession who have their business as well as surgical ability.

DR. ROYAL S. COPELAND, health commissioner of New York City, has been brought into the limelight through a statement in the lay press attributed to him in which he asserts that our "moss covered" code of ethics should be revised, and his reason for the opinion apparently is

founded upon the failure of most of the reputable medical men of New York City to sanction the spectacular work of Professor Lorenz whose reputed philanthropic purposes are open to serious question. At all events the lay press has seized upon the incident as ground for criticism of the medical profession. Some of our Indiana newspapers have taken up the subject, and the *Indianapolis Star* says that "the promotion of the field of the profession as a whole is blocked by the jealousies of the individuals and the cliques within it. * * * There is a great deal of suspicion that a considerable part of the adherence to the 'antiquated' ethics is due to the selfishness of certain members of the profession who care little for the general welfare." Fortunately there are some editors of lay publications who appreciate the reasons for a code of ethics which provide reasonable rules of conduct for medical men, and realize that there is nothing in the code which is inimical to scientific and honorable conduct, and the strictest adherence to conscientious service to suffering humanity. There is nothing really wrong with our code of ethics. The trouble lies with those who for selfish purposes or to sanction unworthy motives in others are quite willing to break the code of ethics and condemn its principles. What we need most of all is a rejuvenation of the code of ethics. The code is just as good and just as applicable now as when first formulated.

BENJAMIN F. BLEDSOE of California, judge of the United States District Court, makes some very pertinent statements concerning the doctor and the Eighteenth Amendment in the January 19th number of the *Bulletin of the Los Angeles County Medical Society*. They should be of interest to every physician in Indiana, and we are publishing them herewith:

Doctors as a class are an ennobled lot. Unreservedly they have consecrated themselves to the highest form of service—service in alleviation of human misery and distress. The new life they usher in; the old life they perhaps prolong; to every life they afford comfort and hope. Whether they are the first reliance or the last resort, they come at our request, prepared for any emergency, ready for any responsibility. The slender thread of life is committed unhesitatingly into their hands; to them we confidently expect the hidden to become the open book. In our anxiety their knowledge becomes an inspiration, their presence a benediction, their skilful ministrations the sure precursor of relief and rest.

But there are those who would turn these men into an organization of mere bartenders, and at that bartenders operating in defiance of law.

By Constitutional mandate, fortified by appropriate Congressional enactment, the use of intoxicating liquors for beverage purposes is absolutely prohibited throughout the United States. Their use for medicinal purposes, pursuant to appropriate regulations, is preserved. To any doctor who really believes that intoxicating liquors possess substantial therapeutic properties, the way is now open, and probably always will be open, in strict conformity to law, to make use of such instrumentalities.

But there is no law, no code of professional ethics, no necessitous condition of the human system and no possible or plausible excuse offering justification for a self-respecting physician to evade, circumvent and deliberately violate the law of the land by providing liquor for a person as a beverage when in truth he does not need it as a medicine.

The simple question now being propounded to the medical profession of America is this: Will you continue to minister to a man's highest needs and thereby share his gratitude and his respect, or will you prostitute your high privileges and pander to his depraved appetite merely that you may get some of his ill spent money?

THE people of Colorado are to be called upon, at the fall election, to vote upon the prohibition of vivisection. The ballot will contain the following caption: "An Act to Prohibit Injurious, Dangerous or Painful Experimental Operations or Administrations Upon Human Beings or Dumb Animals Except to Relieve or Cure Them; Making Exceptions of Persons Consenting to Such Experiments and Providing Penalties for Violations of the Act." "Yes———. No———.", and the unwary voter will be at a disadvantage, for the ballot contains no explanation, but simply appeals to the spirit of mercy. The bill is, of course, the work of the anti-vivisectionists, of which there are now ten societies in the United States, the newest one being the Colorado organization. The parent society seems to be the New York Anti-Vivisection Society—an organization that makes a pretense of mercy and human kindness in order that it may wage propaganda against the medical profession. From the literature which emanates from this Society it is very evident that it is controlled by the drugless practitioners. Some of the pamphlets—in fact many of them—have no reference to vivisection, as will be noted by the following titles: "Shall We Let the Doctors Enslave Us?", "Complete Failure of Medicine in the World War", "Dangers in the Use of Vaccines and Serums", "The Folly and Failure of the Old School Serum-Vaccine Method Versus the Glorious Record of Drugless Doctors in the Influenza Epidemic", "What Would Have Happened Without Osteopathy?", "What Would Have Happened Without Chiropractic?", etc., etc. It is enlightening to note that some of these pamphlets were written by the president of the National Association of Drugless Practitioners. Indiana may, in the none too distant future, be called upon to face just what Colorado is now facing, and Indiana physicians should be making it their business to acquaint the laity concerning the fanaticism, deceitfulness and fraud of these "uplifters" known as anti-vivisectionists.

IN different parts of the country and especially in the East and Middle West, the various uplift schemes proposed by erstwhile leaders of

the medical profession are coming in for not only criticism but severe condemnation. This includes Compulsory Health Insurance, the Sheperd-Towner bill, lay domination of hospitals and the fixing of medical fees by lay persons, community and other clinics under federal, state or municipal control and a number of other Utopian and socialistic ideas which have either been advocated or permitted to become prominent through lack of opposition. Much criticism has been directed toward several of the A. M. A. officers who openly or tacitly have been supporting one or more of these various uplift schemes which, in the ultimate analysis, must prove detrimental to medical profession and public alike. However, some of the A. M. A. officials do not take kindly to criticism and are using the whole machinery of the A. M. A. office to not only voice their disapproval but to discredit the efforts of those who would oppose them. In fact they are trying to make the rank and file of the profession believe that those who dare to criticize officials of the A. M. A. who so long have told us how to act and even how to think, are proposing destructive programs and that their complaints are altogether unworthy of serious consideration. The A. M. A. bosses cry loudly for a *constructive* program when, as a matter of fact, all that is being offered by the opposition is a criticism of a really *destructive* program that has met with considerable favor and support on the part of leaders who ought to be against such socialistic and paternalistic measures as have been offered. Most of the numerous schemes that have been offered and to which the so-called "insurgents" are opposed are positively vicious in their tendencies and cannot help but work harm to the medical profession and to the public as well. They are socialistic and paternalistic in character and we want none of them. The discussion of the subject cannot be stopped by discrediting the men who are opposed to these schemes to socialize medicine, and the A. M. A. officers may find to their sorrow that in using the entire machinery of the A. M. A. to fight openly or by inference the work and opinion of these insurgents is bad policy. Some men get very much peeved if opposed or if anyone disagrees with them. We are confronted with the sins of omission as well as commission on the part of the leaders in our medical profession. We have a right and it is even our duty to oppose those leaders and their plans. The matter is deserving of serious consideration and is not going to be settled by resort to subterfuge, personal abuse, or unfair insinuation on the part of those who are in power in the A. M. A.

A CAMPAIGN is on to raise funds for the Riley Memorial Hospital. Newspapers and solicitors announce that the hospital is to be free to any and all of the children of Indiana. If this means that medical and surgical services are to be free to rich and poor alike, then it is time for medical men and all others interested in fair play and in maintaining the self-respect of all citizens of the state to offer their opposition to the movement. From the first we have had a suspicion that the Riley Memorial Hospital would be a State institution, under State control (probably a lay board), with its policies dictated by lay individuals and its services open to rich or poor on the same terms and, as usual in such schemes, the medical men are the "goats", to say nothing of the tendency to pauperize communities. The worst of this feature is that some of our prominent medical men are said to be responsible for the scheme. If the Riley Memorial Hospital is another link in the chain of evidence which shows the drift toward socializing the practice of medicine then we probably have members of the medical profession in part responsible for the condition. We heartily favor the establishment of the Riley Memorial Hospital, open to any children of the State, but on the distinct understanding that those able to pay shall pay for the services rendered and the fee shall be in keeping with the ability of the patient to pay. There is absolutely no excuse for the establishment of a hospital under State control that furnishes *gratuitous* medical and surgical services to all who come. It is wrong in principle and will prove itself wrong in practice. The Indiana State Medical Association at its last session very properly passed a resolution favoring the establishment and maintenance of the Riley Memorial Hospital for the treatment and care of *indigent* children of the State. In reality it is the indigent children that need such an institution, for the well-to-do are able to secure such attention at any of our good hospitals and under the care of competent physicians and surgeons, whereas the latter institutions, except under very limited conditions, are not patronized by the poor, probably because of the implied obligation that the service and care is to cost something even though but a nominal sum. By all means let us care for the indigent children of Indiana and in the best manner possible, but while we are doing that we should not place the able to pay patients on a charity basis, thus creating the tendency to loss of self-respect and a general pauperization of the community. This is not a selfish argument in favor of members of the medical profession, even though medical men have a right to fight for their economic existence the same as anyone else, but it is a plea for a logical disposition of the matter with the best interests of both the public and the medical profession in view.

FROM the March number of the *Illinois Medical Journal*, we copy some correspondence and comments of the editor:

WAS IT A GREAT DAY FOR MICHIGAN DOCTORS?

January 20, 1922.

To the Editor:

We certainly had some meeting at Detroit. On Tuesday evening from six to one o'clock a. m. we mauled things over at the Detroit Athletic Club, and it was some hot session. We telephoned that President Burton of the University, Hugh Cabot and others could be present at the Councilors' meeting the next day. They were obliged to get up long before daylight and drive sixty miles in order to be present at our meeting at 8:30 in the morning. It was a case of Mohammed coming to the mountain instead of the mountain going to Mohammed. They brought the peace dove with them.

President Burton and Dr. Cabot said that they wanted to be with us, that they are against State Medicine, Compulsory Health Insurance, Community Hospitals, etc. They said further that through the extension service of the University they will deliver lectures all over the state of Michigan on what general medicine has done in the past, what it is doing at present and what it will do in the future: that they will not say a word against any cult or sect, which I think is very wise.

It is my belief that January 11 was one of the greatest days for medicine in the state of Michigan for many years. I am thoroughly convinced that the victory that the State Medical Society obtained over the University the other day at Detroit is largely due to the work of yourself and Dr. Bulson of Indiana. I wish that you would congratulate Dr. Bulson for me. H. W. A.

Note and Comment:—Evidently some of the Michigan doctors feel that Burton and Cabot, *et al.*, have abandoned their former socialistic plans. Like the Scotchman, "I hae me doots". The leopard cannot change his spots; we are from Missouri and in this case have to be shown. All our life we have been watching the performance of medico-politico acrobats, jugglers, trained seals and tight rope walkers, and we feel that we are perfectly competent to recognize such performers when we see them.

Burton and Cabot have not reformed. At the meeting referred to above they camouflaged and sidestepped completely the fact that in the past they have been advocating socialized medical schemes, such as community clinics which they proposed, which would be a direct step toward placing the practice of medicine in Michigan under state control.

We believe with Dr. Albert E. Bulson, Jr., editor of the *Journal of the Indiana State Medical Association*, in his analysis of the Michigan proposition, when he says "that the community clinic which they proposed would be a direct step toward placing the practice of medicine in Michigan under state control. In fact, they boldly stated that these clinics in various sections of Michigan were to be conducted and controlled by the University, the latter of course being under state control. Just what the medical men of Michigan are thinking of to let the University of Michigan pull off a stunt of that kind is more than I can understand. Furthermore, if the University of Michigan, as avowed in their statement just published, is to confine itself to teaching, why in the name of heaven have they arranged for enormous hospital facilities far beyond the needs of teaching purposes? There is a 'joker' in the whole program and the medical profession of Michigan may wake up when it is too late."

The Indiana State Journal passes the remark: "At last Michigan is Waking Up." Humph, strange how, when one is stretching and yawning and trying to become accustomed to the light of a new day, even though it is 11 a. m., that he labors under the impression that the rest of the world is just rising with him. Michigan has been awake many hours, Indiana. It has passed the early stage of criticism and fault-finding and is attempting to offer something that is constructive. Shake-a-leg, Hoosier brother; catch up with the crowd and let us have the benefit of your constructive advice. Let us have your aid in remodeling and revamping. What have you to offer?—*Journal Michigan State Medical Society*, March, 1922.

The above refers to our editorial note in a recent number of THE JOURNAL in which we called attention to what seems to be an awakening of the medical profession of Michigan to the dangers of socialized medicine as proposed and to an extent carried out by the University of Michigan, and by inference criticized by the editor of the *Journal of the Michigan State Medical Society* in recent numbers of his journal. We desire to remind our brother editor in Michigan that he was *not* awake when he permitted the University of Michigan to propose, months ago, some socialistic schemes which at that time he never criticized or opposed so far as we know. It was only after we complained about these socialistic schemes because both directly and indirectly they affected the whole medical profession, and the complaint was reiterated by prominent members of the medical profession of Michigan and elsewhere, that the editor of the *Journal of the Michigan State Medical Society* began to wake up. We are not quite satisfied that even yet he is awake, for unless we are badly mistaken he has been hypnotized by what apparently is a "turn about face" on the part of the authorities of the University of Michigan. However, as the editor of the *Illinois Medical Journal* says in commenting on the same subject, "I hae me doots" about the change of heart of those who have been advocating schemes that ultimately would annihilate private medical practice. It is a little amusing to hear those who have been criticized complain about fault-finders and ask for something *con*structive. Why, bless your soul, brother, we are busy enough right now trying to head off *de*structive and vicious measures that have been either advocated or supported by some of the leaders in

the medical profession, and in evidence we mention Compulsory Health Insurance, the Sheperd-Towner Bill, lay domination of hospitals and medical fees, and, last but not least, the effort to establish community clinics under state control—a most vicious project having inception in the minds of the authorities of the University of Michigan, publicly advocated and never receiving one word of disapproval from you until this Journal commented upon the matter. A *con*structive program will come soon enough when we pry some of you fellows loose from various uplift schemes that threaten the destruction of the private practice of medicine. Catch up with the crowd! Lord bless you, brother Editor, we don't want to catch up with a crowd that is trying to foist state controlled community clinics upon us unless to "catch up" gives us an opportunity to change the course of those who are leading themselves as well as the rest of us into danger.

DEATHS

SAMUEL A. KENNEDY, M.D., died at his home in Indianapolis at the age of 92 years.

WILLIAM H. BANKS, M.D., died at his home in Waymansville, March 2, at the age of 84 years.

HENRY W. JONES, M.D., died March 3 at his home in Spiceland. Dr. Jones graduated from the Cincinnati College of Medicine and Surgery in 1875.

W. N. WILLIAMSON, M.D., died Tuesday, February 21, at his home in Indianapolis. Dr. Williamson graduated from the Medical College of Indiana, Indianapolis, in 1880.

WILLIAM P. KOCHENOUR, M.D., died at his home near Rego at the age of 74 years. Dr. Kochenour graduated from the Hospital College of Medicine, Louisville, Kentucky, in 1884.

OLIVER F. GRAY, M.D., of Spencer, died recently after a short illness. Dr. Gray graduated from the Indiana Medical College, Indianapolis, in 1878. He was a member of the Owen County Medical Society and the Indiana State Medical Association.

SAMUEL M. VORIS, M.D., died February 21, 1922, at his home in Columbus, aged seventy-six years. Dr. Voris was a graduate of the Jefferson Medical College, of Philadelphia, and was a member of the Bartholomew County Medical Society and the Indiana State Medical Association.

CHARLES C. GIVENS, M.D., aged 72 years, died as the result of an accident when his automobile was struck by a train. Dr. Givens graduated from the Louisville Medical College in 1882 and was a member of the Vigo County Medical Society and the Indiana State Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in THE JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

THE Decatur County Medical Society held a banquet at Vevay, February 16.

DR. R. F. BLOUNT, of Wabash, celebrated his ninety-first birthday February 12.

DR. JOSEPH H. CASPER has opened an office in the Steinkemp Building, Jasper.

DR. W. T. LAWSON was elected Health Commissioner of Hendricks County in January.

THE Lawrence County Medical Society held its regular meeting at Mitchell, February 1.

DR. W. F. BUTLER, of Cayuga, was injured when he fell down a flight of steps February 9.

A WARD for colored patients is to be added to the Irene Byron Tuberculosis Hospital, Fort Wayne.

DR. D. R. GOOD, of Boggstown, has removed to Newport, where he will take up the practice of medicine.

DR. MILES F. PORTER, SR., of Fort Wayne, has been made a member of the Indiana State Anatomical Board.

DR. M. MAY ALLEN has been made assistant director of the child hygiene division of the State Board of Health.

THE Putnam County Orphans' Home at Greencastle was destroyed by fire, the loss being estimated at approximately fifteen thousand dollars.

THE Elkhart County Medical Society held its annual meeting at South Bend, February 4. More than one hundred physicians attended the meeting.

DR. J. H. ALLEN, of Patricksburg, has purchased the office and home of Dr. Black at Fishers and will locate there for the practice of medicine.

DR. HENRY LOGAN, of Rushville, was injured February 20 when the automobile in which he was riding was struck by a train. The injuries were not serious.

THE Orange County Medical Society held a meeting February 7 at Orleans. A paper was presented by Dr. Wilson on "Vaccines and Organo-therapy".

DR. RAYMOND STENGER, of the medical staff of the National Military Sanitarium, near Marion, and Miss Inez Worley, of Marion, were married February 9.

DR. LOUIS A. BOLLING, of Attica, has accepted a position with the government and will be stationed at the clinic for veterans of the World War at Washington, D. C.

THE annual meeting of the Daviess-Martin County Medical Society was held February 22 at Washington. Dr. W. H. Foreman, of Indianapolis, presented a paper.

THE Madison County Medical Society held its meeting at Anderson, February 22. A paper on "Non-Infectious Diseases and Anaphylaxis" was presented by Dr. W. H. Miley.

THE Marion County Medical Society held a meeting at Indianapolis, February 26. Dr. E. E. Rosenow, of the Mayo Clinic, presented an illustrated lecture on "Focal Infections".

THE death rate of New York State for the year 1921 is the lowest ever recorded for it, being 12.2 per thousand of population. The rate in 1920 was 13.8, and in 1914, 14.7.

PLANS have been approved by the Lake County board of commissioners for a modern county tubercular sanitarium to be situated on a 120 acre tract of land near Crown Point.

A CAMPAIGN has been started to raise $350,000 for the building of a 100-room wing, contagious department, and a nurses' training school at St. Elizabeth's Hospital, Lafayette.

THE Huntington County Medical Society held its annual banquet February 7 at Huntington. Papers were presented on "Dislocation of the Shoulder Joint", by Dr. W. C. Moore, and "Treatment of Cancer", by Dr. B. F. Kirkland.

THE Wells County Medical Society held a meeting at Bluffton, February 21. Dr. E. E. Morgan, of Fort Wayne, presented a paper on "Pruritis Anis" and Dr. W. D. Calvin, of Fort Wayne, read an article on venereal disease.

DR. GEORGE T. MCCOY, of Columbus, has been made president of the Indiana Tuberculosis Society to succeed Dr. Eric Crull, of Fort Wayne, at the closing session of the eleventh yearly conference in Indianapolis.

ARRANGEMENTS have been made by Goshen physicians and the management of the Goshen Hospital Association to purchase an x-ray equipment at a cost of $3,500, which will soon be installed in the hospital.

A JOINT meeting of the Bartholomew and Jackson County Medical Societies was held February 2 at Seymour. Dr. A. G. Osterman, of Seymour, presented a paper on "Pneumonia and Its Treatment".

THE Clinton County Medical Society held its regular monthly meeting February 2 at Frankfort. Dr. W. C. Mount, of Kirklin, presented a paper, the subject of which was "Early Diagnosis and Treatment of Surgical Cases".

THE Kosciusko County Medical Society held its regular monthly meeting January 31, at Warsaw. A paper on "Control of Venereal Diseases" was presented by Dr. J. G. Royse, of Indianapolis.

A BOND issue of $150,000 for the construction of additional hospital facilities at the Marion County Hospital for the Insane at Julietta was approved by the Marion county council at a recent meeting.

Archives of Occupational Therapy is a new periodical, the official organ of the American Occupational Therapy Association. It is edited by Dr. William R. Dunton, and will be published bimonthly.

DR. F. W. CREGOR, of Indianapolis, announces that he has associated with him Dr. F. M. Gastineau, formerly of Bellevue and New York Skin and Cancer Hospitals, in the practice of dermatology and allied conditions.

THE annual meeting of the Children's Aid Association was held in Indianapolis February 13. Dr. C. C. Carstens, of New York, director of the Child Welfare League of America, spoke on "Newer Movements in Child Welfare".

DR. HUBERT WORK, President of the American Medical Association, who has been serving as assistant postmaster general during the present administration, has been promoted to postmaster general to succeed Mr. Hayes, resigned.

THE regular meeting of the Muncie Academy of Medicine was held Friday, February 10. A paper on "Early Signs of Neuro-Syphilis" was presented by Dr. L. D. Carter, of Indianapolis, and Dr. C. A. Ball presented a paper on "Infant Feeding".

THE Delaware-Blackford County Medical Society held its regular meeting at Muncie, February 3. A paper was presented by Dr. William Engleboch, of St. Louis, on "Diagnosis and Treatment of Disorders of the Endocrine Glands".

DR. B. D. MYERS, of Bloomington, has been made a member of a committee of the Association of American Medical Colleges which is to draft a course of study that will serve as a basis for the curriculums of the leading medical schools of the United States.

PROF. VERNON LYMAN KELLOGG, zoologist and secretary of the National Research Council, Washington, D. C., and John W. Davis, attorney, New York City, formerly ambassador to Great Britain, have been elected trustees of the Rockefeller Foundation.

THE next meeting of the Northern Tri-State Medical Association will be held at Ann Arbor, Michigan, Tuesday, April 11. The number of papers to be presented has been limited that the program will not be crowded. The University is arranging some excellent clinics for the morning session.

DR. K. K. WHEELOCK, of Fort Wayne, will sail from New York on March 21 to visit Italy, Australia, Germany, Switzerland, France, England, Scotland, Belgium and Holland. Dr. Wheelock will visit his daughter, who is in Sicily, and expects to take up special study of the eye, ear, nose and throat in Vienna.

IT has been announced that the General Education Board of the Rockefeller Foundation has appropriated during the last fiscal year $18,210,353 for colleges and universities, $12,029,513 for medical schools, and $646,000 for negro education. Since its establishment in 1902 this Board has appropriated $89,017,872.

ARRANGEMENTS have been completed for a health exposition to be held at Indianapolis in May. Exhibits will be presented by more than one hundred health educational organizations throughout the United States. The exposition is an outgrowth of the Indianapolis Public Health Institute which was held February 13-18.

WESTERN RESERVE UNIVERSITY is the recipient of a gift of a sufficient amount of money, from Samuel Mather, to erect new medical school buildings which are to be "the finest in the country". No amount is specified in the gift, but the architect's estimate calls for approximately $2,530,000. Construction is to be begun this spring.

THE regular monthly meeting of the LaPorte County Medical Society was held February 10 at the LaPorte Y. M. C. A. Dr. Burton Haseltine, Professor of Head Surgery, Hahn Medical College, presented a paper on Sinus Infections, the discussion of which was led by Drs. H. L. Brooke and M. S. Smith. Clinical cases were presented by local members of the Society.

INFLUENZA statistics for the first six weeks of 1922 show a greater number of cases of this disease than a similar period last year, but the present situation is not at all comparable to conditions existing in 1919-1920. For the first six weeks of 1922, 28,075 cases of influenza were reported in 24 states; for 1921, in 22 states, there were 4.143 cases; and for 1920, in 23 states, there were 477,289 cases.

DR. FREDERICK R. GREEN, who has been connected with the headquarters office of the American Medical Association since the year 1905, and has served as secretary of the Council on Health and Public Instruction since its organization in 1910, has resigned, the resignation taking effect on March 31. Dr. Green has formed a partnership with Dr. C. St. Clair Drake and Dr. John Dill Robertson for the publication of *Health*, a popular monthly magazine.

UNDER an executive order recently issued by President Harding, surplus medicines and medical, surgical and hospital supplies held by the War, Navy and Treasury departments and the Shipping Board will be made available for the Russian relief. The supplies will be delivered to the American Relief Administration within four months' time, and will not exceed $4,000,000 in original cost to the Government. The relief association is authorized to make the distribution of the materials through its own agencies or those of other relief organizations operating in Russia which may be found in a better position to distribute the supplies to centralized localities.

DURING February the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: Persson Laboratories—Bacillus Coli Antigen (No. 50)-Persson, Furunculosis Vaccine Mixed (No. 37)-Persson, Gonococcus Antigen (No. 47)-Persson, Staphylococcus Aureus Antigen (No. 49)-Persson, Streptococcus Antigen (No. 48)-Persson, Pneumonia Vaccine (No. 36)-Persson. Powers-Weightman-Rosengarten Co.—Novarsenobenzol-Billon. G. H. Sherman—Whooping Cough Vaccine-Sherman, Mixed Typhoid Vaccine-Sherman, Acne Staphylococcus Vaccine-Sherman. Winthrop Chemical Co.—Alypin.

THE TRUTH ABOUT MEDICINES

PROPAGANDA FOR REFORM

BUTYN, A NEW SYNTHETIC LOCAL ANESTHESIA.—A committee of the A. M. A. Section on Ophthalmology reports to the Council on Pharmacy and Chemistry on the clinical use of butyn in operations on the eye, nose and throat. The committee finds butyn preferable to cocain as an anesthetic in operation on the eye. One member of the committee also reports favorably on its use in operations on the nose and throat. As a result of the clinical and experimental use of butyn, the committee arrives at the following conclusions: 1. It is more powerful than cocain, a smaller quantity being required. 2. It acts more rapidly than cocain. 3. Its action is more prolonged than that of cocain. 4. According to our experience to date, butyn in the quantity required is less toxic than cocain. 5. It produces no drying effect on tissues. 6. It produces no change in the size of the pupil. 7. It has no eschemic effect and therefore causes no shrinking of tissues. 8. It can be boiled without impairing its anesthetic efficiency.—(*Jour. A. M. A.*, Feb. 4, 1922, p. 345).

WILLARD EALON OGDEN, SPECIALIST IN PROCTOLOGY.—Dr. Willard E. Ogden, Chicago, claims to be a specialist in proctology, author of "Improved Method of Treating Rectal Diseases", to have been associated with the leading proctologists of America, and to have developed a method of office treatment which is not taught by any other practitioner. He offers to instruct physicians in his methods. In 1914 Ogden advertised in Chicago newspapers to cure piles. In 1921 Ogden had a copyrighted mail-order course of the treatment of rectal diseases by improved methods. Careful search fails to disclose that Dr. Willard E. Ogden has ever distinguished himself in the practice of specialties in which he now wishes to instruct physicians, that he has never published a paper on any phase of medicine or surgery, or that he has been associated with the leading proctologists of America.—(*Jour. A. M. A.*, Feb. 4, 1922, p. 368).

MERCURIC CACODYLATE.—As cacodylates have been found practically worthless in the treatment of syphilis, mercuric cacodylate must be considered as merely an administration form of mercury. It contains but one-half as much mercury as mercuric salicylate. The two preparations cannot be compared with each other as to local or general action for the reason that the cacodylate is soluble while the salicylate is practically insoluble. The cacodylate has to be administered daily to maintain adequate action. Mercuric salicylate is a favorite drug because of the argument that, being insoluble, it forms a depot of mercury in the tissues so that a week's dose may be administered at one time. To keep the patient under as continuous mercurilization as would be secured by the ordinary dose of 0.10 Gm. of mercuric salicylate given once a week, six doses of 0.04 Gm. of cacodylate would have to be given: in other words, a daily dose excepting Sunday. The pain and induration induced by mercuric salicylate is the price the patient must pay for the convenience of weekly administration.—(*Jour. A. M. A.*, Feb. 11, 1922, p. 452).

STYPTYSATE NOT ADMITTED TO N. N. R.—Styptysate, according to the advertising of Ernst Bischoff Co., Inc., is "obtained by dialysis from Bursa Pastoris (Shepherd's (sic) purse)". It is claimed to be "The Remedy for Hemorrhages", to be "Superior to Ergot and Hydrastis", "of particular advantage in Menorrhagia and Metorrhagia" and to have been "found of great value in vesicle hemorrhages and hemorrhages from mucous membranes in general". According to the label, Styptysate is "made in Germany", but the name of the German manufacturer is not given. According to German publications, a proprietary called Styptysate and made from shepherd's purse—a common weed—was used in Germany as a substitute for ergot when this drug was not obtainable. On the assumption that the product discussed in German publications is the Styptysate marketed in the U. S., the best that can be said for it is that, during a shortage of ergot, it was used in place of that established drug. The Council on Pharmacy and Chemistry reports that Styptysate (Ernst Bischoff & Co., Inc.) is inadmissible to New and Nonofficial Remedies because its composition is semisecret and indefinite, and there is no evidence that its uniformity and strength is controlled; further, it is inadmissible because the therapeutic claims advanced for it are exaggerated and unwarranted and because there is no evidence that it possesses any advantage over established drugs, such as the biologically standardized fluidextract of ergot or the definite ergot preparations admitted to New and Nonofficial Remedies.—(*Jour. A. M. A.*, Feb. 11, 1922, p. 450).

IRON THERAPY.—Iron has so long been administered in some form or other in the treatment of anemia that one might well suppose that its function in the regeneration of blood had been clearly determined. This is far from being the case. Last year, Whipple and his associates reported that iron given as Blaud's pills had no influence on the rate of blood regeneration in secondary anemia produced in animals. They reported that there is some experimental evidence for the administration of blood in secondary anemia, but state that whole red cells or hemoglobin given by mouth in the form of a dry powder do not appear to influence profoundly the blood regeneration curve. Their experiments show that hemoglobin has a distinct influence on blood regeneration, but not sufficient to warrant its use in uncomplicated second-

ary anemia in view of the favorable action of meat and other diet factors. Musser has studied the effect of inorganic iron in a type of anemia representing more closely what is seen in clinical medicine. He found that ferrous carbonate failed to produce any alteration of the experimental hemorrhagic anemias. All of the more recent evidence indicates that the iron is of paramount importance in red blood cell regeneration.—(*Jour. A. M. A.*, Feb. 18, 1922, p. 512).

Urotropin was removed from the list of articles accepted for New and Nonofficial Remedies because Schering & Glatz, Inc., refused to place the U. S. Pharmacopeia name hexamethylenamine (hexamethylenamina) on the label and in its advertising so as to make clear to physicians the identity of the product, and because it was sold under therapeutic claims which the Council held unwarranted. An advertising pamphlet sent to physicians in 1921 contains a number of unwarranted statements; particularly objectionable are the claims made for the use of Urotropin as an antiseptic in body fluids that are alkaline, such as the cerebro-spinal fluid, bile, aqueous humor of the eye, saliva, the excretions caused by middle ear infection and other excretions of the nasal, bronchial, laryngeal and mucous membranes. The lack of efficacy of hexamethylenamine in alkaline secretions is generally admitted, and the clinical references to the use of hexamethylenamine in the pamphlet are obsolete. In the introduction to the pamphlet, Schering & Glatz state that they are well acquainted with the scientific research work discrediting the efficiency of hexamethylenamine in non-acid media, but that they feel that the accumulated evidence for its efficacy in such conditions should not be "brushed aside". However, the pamphlet is not made up of quotations, but of unqualified statements. With one exception, all reference to the antiseptic properties of the drug in alkaline media are previous to 1913, that is, before the importance of reaction of the medium was fully appreciated. To quote these earlier articles, without regard to the later work which in most eyes discredited them, constitutes in effect an exploitation of this brand of hexamethylenamine under unwarranted therapeutic claims.—(*Jour. A. M. A.*, Feb. 18, 1922, p. 531).

LIPOIDAL SUBSTANCES (HOROVITZ BIO-CHEMIC LABORATORIES CO.) NOT ADMITTED. According to the Horovitz Bio-Chemic Laboratories Co. (A. S. Horovitz, president), Horovitz has discovered or developed a treatment for drug addiction. This is marketed by the Horovitz Bio-Chemic Laboratories as Lipoidal Substances. The treatment consists, first, in the withdrawal of the narcotic; second, in free catharsis; and third, in the intramuscular injection of the preparation. In its request for the admission of Lipoidal Substances to New and Nonofficial Remedies, the Horovitz Bio-Chemic Laboratories Co. informed the Council on Pharmacy and Chemistry that the product contained lipoids of plant origin, vitamines (water-soluble) of plant origin and nonspecific plant proteins. While the communication abounded in generalities, it gave neither the identity nor character of the lipoids, of the vitamines, nor of the nonspecific protein, nor their quantities or the methods for their control. The firm presented no evidence that the injection of Lipoidal Substances produces any effect other than by suggestion. The Council declared Lipoidal Substances inadmissible to New and Nonofficial Remedies because the composition is essentially secret and because the curative claims are unsubstantiated and therefore unwarranted.—(*Jour. A. M. A.*, Feb. 25, 1922, p. 600).

BIO-CHEMIC LABORATORIES' PRODUCTS.—The Bio-Chemic Laboratories, Chicago and Los Angeles, send out the following advertising: 1. "Salvarsan and Mercury Without the Needle". In this pamphlet the use of Salv-Absorbs and Merc-Absorbs, preparations for the rectal administration of arsphenamine and mercury, respectively. 2. "Something New in Glandular Therapy—Caplets". This circular declares that "Caplets make possible the preparation of any pluriglandular combinations in your office * * * Your office girl can make them up for you". 3. "Why Gland Transplantation?" A circular devoted to "Orch-Absorbs" which is said to be "a preparation of interstitial glands for intra-rectal administration". No preparation of the Bio-Chemic Laboratories has been accepted for New and Nonofficial Remedies. The Council on Pharmacy and Chemistry, however, has published a report on another proprietary form of administering arsphenamine by rectum. This brings out the lack of evidence for the efficacy of this method of arsphenamine administration. The pluriglandular "Caplet" medication is a form of shotgun therapy that has been the subject of a report of the Council on Pharmacy and Chemistry and has been discussed editorially.—(*Jour. A. M. A.*, Feb. 25, 1922, p. 603).

NEW AND NONOFFICIAL REMEDIES

ANIMAL EPIDERMAL EXTRACT ALLERGENS-SQUIBB.—Powders representing the alkali-soluble protein from the hair and epidermis of animals or from the feathers of fowls. Animal Epidermal Extract Allergens-Squibb are employed for the diagnosis of asthma or perennial rhinitis. The patient's susceptibility may be tested in the same manner as that employed for pollen extracts. They are not intended for treatment. The following allergens have been accepted: Burro Dander Allergen-Squibb, Burro Hair Allergen-Squibb, Cat Dander Allergen-Squibb, Cat Hair Allergen-Squibb, Chicken Feathers Allergen-Squibb, Cow Dander Allergen-Squibb, Cow Hair Allergen-Squibb, Dog Dander Allergen-Squibb, Dog Hair Allergen-Squibb, Duck Feathers Allergen-Squibb, Goose Feathers Allergen-Squibb, Horse Dander Allergen-Squibb, Horse Hair Allergen-Squibb, Rabbit Dander Allergen-Squibb and Rabbit Hair Allergen-Squibb. E. R. Squibb & Sons, New York.—(*Jour. A. M. A.*, Feb. 4, 1922, p. 349).

BACTERIAL ALLERGENS - SQUIBB.—Protein extracted from bacterial cells. Bacterial proteins have been used cutaneously for the diagnosis of anaphylaxis to the metabolic products from specific bacteria. Their utility is debatable. The following allergens have been accepted: Bacillus Coli Allergens- Squibb, Bacillus Pertussis Allergen-Squibb, Bacillus Typhosus Allergen-Squibb, Catarrhalis Allergen-Squibb, Gonococcus Allergen-Squibb, Pneumococcus-I Allergen-Squibb, Pneumococcus-II Allergen-Squibb, Pneumococcus-III Allergen-Squibb, Pneumococcus-IV Allergen-Squibb, Staphylococcus Albus Allergen-Squibb, Staphylococcus Aureus Allergen-Squibb, Streptococcus Pyogenes Allergen-Squibb, and Streptococcus Viridans Allergen-Squibb. E. R. Squibb & Sons, New York.—(*Jour. A. M. A.*, Feb. 4, 1922, p. 349).

BUTYN.—Paraminobenzoyl-gammadinormal butylaminopropanol sulphate. It is a local anesthetic proposed as a substitute for cocain, particularly in surface anesthesia, as for the eye, nose and throat. It has the advantage of acting through intact mucosæ almost as effectively as cocain. On the normal human eye, a 0.5 percent solution of butyn is less effective than a 1 percent solution of phenacain, but more efficient than a 1 percent solution of cocain or a 1 percent solution of eucain. Butyn has been used with success in practically all operations on the eye and in some operations on the nose and throat. Butyn is supplied in solution and also as Butyn Solution, 2

percent: Butyn Tablets. 0.2 gm., and Butyn and Epinephrin Hypodermic Tablets. The Abbott Laboratories, Chicago.

SOLUTION OF POST-PITUITARY-G. W. CARNRICK CO.—An extract of the posterior lobe of the pituitary body of cattle, standardized to have the same strength as liquor hypophysis U. S. P. For a discussion of the uses and dosage see New and Nonofficial Remedies under Pituitary Gland and Solution of Hypophysis. Solution of Post-Pituitary is supplied in 1 Cc. ampules. G. W. Carnrick Co., New York.

PITUITRIN "O".—An extract of the posterior lobe of the pituitary of cattle, approximately 2½ times the strength of Solution of Hypophysis U. S. P. For a discussion of the actions and uses see article Pituitary Gland. New and Nonofficial Remedies 1921, p. 219. Pituitrin "O" is supplied in 0.5 Cc. and 1 Cc. ampules. Parke, Davis & Co., Detroit.—*(Jour. A. M. A.*, Feb. 11, 1922, p. 431).

ALYPIN.—The hydrochlorid of 2-benzoxy-2-dimethyl-amino-methyl-1-dimethyl-amino-butane. Alypin is a local anesthetic claimed to be equal to procain, but is not a mydriatic. It is said not to produce disturbance of accommodation and to be less toxic than cocain. But the evidence as to the relative toxicity of alypin and cocain is conflicting. Alypin is used in solutions having about the same strength as solution of cocain hydrochlorid. Winthrop Chemical Co., New York.

NOVARSENOBENZOL-BILLON.—A brand of neoarsphenamine-N. N. R. Marketed in 0.6 Gm. and 0.9 Gm. ampules. Manufactured under license from Les Etablissements Poulenc Freres, Paris, and the Chemical Foundation, Inc. Powers-Weightman-Rosengarten Co., Philadelphia.

WHOOPING COUGH VACCINE-SHERMAN.—Pertussis bacillus vaccine (see New and Nonofficial Remedies 1921, p. 308) marketed in 10 Cc. vials. G. H. Sherman, Detroit.

MIXED TYPHOID VACCINE-SHERMAN.—A typhoid vaccine (see New and Nonofficial Remedies 1921, p. 310) marketed in 10 Cc. vials each cubic centimeter containing 1,000 million killed typhoid bacilli and 500 million each of paratyphoid bacilli A and B. G. H. Sherman, Detroit.

ACNE STAPHYLOCOCCUS VACCINE-SHERMAN.—A mixed vaccine (see New and Nonofficial Remedies 1921, p. 314) marketed in 10 Cc. vials each cubic centimeter containing 40 million killed acne bacilli and 1,000 million killed Staphylococcus albus. G. H. Sherman, Detroit.

BACILLUS COLI ANTIGEN (No. 50)-PERSSON.—A colon bacillus vaccine (see New and Nonofficial Remedies 1921, p. 299) marketed in 20 Cc. vials, each cubic centimeter containing 1,000 million killed colon bacteria. Persson Laboratories, Mount Clemens, Michigan.

FURUNCULOSIS VACCINE MIXED (No. 37)-PERSSON.—A staphylococcus vaccine (see New and Nonofficial Remedies 1921, p. 306) marketed in 20 Cc. vials, each cubic centimeter containing 2,000 million killed staphylococcus aureus and 2,000 million killed staphylococcus albus. Persson Laboratories, Mount Clemens, Michigan.

The Ten Commandments *of* Medical Ethics

By DR. FRANK B. WYNN

Reproduced from "The Physician"

Artistically printed in colors and handsomely illuminated by an especially designed border illustrating the History of Medicine in Symbolism. Size 17 x 22 inches, suitable for framing; price, postpaid, $2.00. For sale by F. E. Dillan, publisher, 817 Hume-Mansur building Indianapolis, Indiana.

A Bloodless Field is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 **Suprarenalin Solution** slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work **Pituitary Liquid** (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's **Sterile Catgut Ligatures** are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

BALTIMORE—MARYLAND

(Continued from page 108)

STAPHYLOCOCCUS AUREUS ANTIGEN (No. 49)-PERSSON.—A staphylococcus vaccine (see New and Nonofficial Remedies 1921, p. 306) marketed in 20 Cc. vials, each cubic centimeter containing 3,000 million killed staphylococcus aureus. Persson Laboratories, Mount Clemens, Michigan.

GONOCOCCUS ANTIGEN (No. 47)-PERSSON.—A gonococcus vaccine (see New and Nonofficial Remedies 1921, p. 300) marketed in 20 Cc. vials, each cubic centimeter containing 3,000 million killed gonococci Persson Laboratories, Mount Clemens, Michigan.

STREPTOCOCCUS ANTIGEN (No. 48)-PERSSON.—A streptococcus vaccine (see New and Nonofficial Remedies 1921, p. 309) marketed in 20 Cc. vials, each cubic centimeter containing 1,000 million killed streptococci. Persson Laboratories, Mount Clemens, Michigan.

PNEUMONIA VACCINE (No. 36)-PERSSON.—A pneumococcus vaccine (see New and Nonofficial Remedies 1921, p. 304) marketed in 30 Cc. vials, each cubic centimeter containing 8,000 killed pneumococci, Types I, II, III and Group IV in equal proportions. Persson Laboratories, Mount Clemens, Michigan.—(*Jour. A. M. A.*, Feb. 25, 1922, p. 581).

BOOK REVIEWS

GENERAL PATHOLOGY—An Introduction to the Study of Medicine. Being a Discussion of the Development and Nature of Processes of Disease. By Horst Oertel, Strathcona Professor of Pathology and Director of the Pathological Museum and Laboratories of McGill University and of the Royal Victoria Hospital, Montreal, Canada. Cloth, Pp. 357, with Illustrations. Price $5.00 net. New York: Paul B. Hoeber.

Oertel has given us, in these 357 pages, a text-book which the average practitioner can read with both pleasure and profit. This statement will not apply to many text-books on the subject of general pathology. The book gives, in a compact form, an illuminating picture of the present status of general pathology. The author's style is commendable. A reviewer in the J. A. M. A. criticized this book rather severely; it must be admitted that much of this criticism was justifiable. It was inexcusable for the author to have misspelled names and words, to have made no mention of the water transmission of typhoid, and to have omitted all reference to the flea in connection with rat plague. Most of the errors are found in connection with subjects which pertain to bacteriology. The balance of the book is of sufficient value to justify the reviewer in recommending it to the readers of THE JOURNAL.

SOCIAL DISTINCTIONS

Little Elnore—What does your papa do?

Little Florence—He's a horse doctor.

"Then I guess I'd better not play with you; I'm afraid you don't belong to our set."

"I don't see why. What does your papa do?"

"He's a veterinary surgeon."—*Cincinnati Times-Star.*

6 Points to Remember when Choosing Mead's Dextri-Maltose to Modify Cow's Milk for Bottle Babies

Point No. 1

It does not have directions on the package, as these interfere with the doctor's instructions to mothers.

Point No. 2

It is not advertised in the women's magazines and other lay papers, as this is unethical.

Point No. 3

Literature on infant feeding is not mailed to mothers.

MEAD'S
DEXTRI-MALTOSE
(Dextrins and Maltose)

Has been used by thousands of physicians for over 10 years because it gives gratifying results in infant feeding and because it is a strictly ethical product.

A Three Way Winner

10 days' trial will prove its value to the doctor, the mother and the infant.

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information regarding their use reaches the mother only by written instructions from her doctor on his private prescription blank. Literature furnished only to physicians.

Point No. 4

It contains the proper food salts. Sodium Chloride for average babies; Potassium Bicarbonate for constipated babies.

Point No. 5

It contains no protein, cellulose or fat. It is used as a malt sugar and a sugar it should be.

Point No. 6

It contains
Dextrins 43%
Maltose 52%
Moisture 5%
These proportions were selected by Pediatricians.

CALCREOSE

"CREOSOTE and * * * * are used internally as intestinal and urinary antiseptics, as stimulant expectorants and in the treatment of tuberculosis. Their local irritant actions often interfere with their internal administration." (New and Nonofficial Remedies, 1921, p. 89.)

CALCREOSE is a mixture containing in loose chemical combination approximately equal weights of creosote and lime (calcium creosotate.)

CALCREOSE administered internally has the same actions and uses as creosote, but does not readily produce gastric distress, nausea and vomiting even when large quantities are taken for comparatively long periods of time.

CALCREOSE may be given in the form of solution or tablets.

BILIARY INFECTIONS*

JOHN W. SLUSS, M.D.
INDIANAPOLIS, INDIANA

Fashions, fancies, and fads hold sway in medicine as elsewhere. Illustrations are not far to seek.

In times past, it has been (to cite a single example) the fashion with our predecessors of a particular period to attribute most of the body's ills to some perversity of the liver, or to the humors in some occult manner arising therein. The liver bulked so large in their pathological notions as to overshadow all else. Even so, it is not certain that they may not have had something the better of us who, in these latter days, in our disease summations, fail in such degree to take this important viscus into account.

Liver Relations and Functions. Its morphological and anatomical relations are immensely significant. No disorder in the digestive tube can be properly considered apart from it, for like the pancreas, it is embryologically a very special elaboration of the same primitive cell groups that form the epithelia of the stomach and duodenum. The operation of its cells profoundly interests those of other organs. It seems to be demonstrated, even, that the brain itself cannot exist without the liver. A normal liver function is the "sine qua non" to normal brain function. Indeed, lay writers of all times have imagined an intimate connection between quality of thought—in other words, temperament—and certain hepatic states, so that this empiric notion seems now to have acquired a scientific confirmation. The liver, more broadly speaking, has greatly to do with the whole metabolism of the body. In addition it is a large factor in body defense—an important fact not sufficiently emphasized. On the metabolic side it is intimately concerned with the last elaborations of the proteid food substances—the amido acids—on their way to the tissue cells. From the carbohydrates it elaborates glycogen which becomes stored-up energy. Finally it furnishes bile, a part of the function of which is to split up the hydrocarbons and prepare them for absorption and assimilation.

Its *defense function* consists in straining many noxious substances out of the blood, such as bacteria, protozoa and the toxic products of imperfect tissue oxidation,—a function so important we might well make it one of our fads. In a word, the liver, unlike any other, is equally important as an organ of secretion and of excretion; this is a concomitance of its unique relation to the circulatory system—a relation which should always be insisted upon. Its proper nutrition (at any rate of its parenchyma) is not derived from the general circulation as in the case of all other organs, but is derived directly from the portal vein. In the foetus this arrangement results in a great preponderance of hepatic growth, so that the fetal liver is large, out of all proportion to the other units of the organism.

Which of the liver's elaborations are secretions and which excretions? Physiologists are not clear on this point, particularly in the case of bile. Bile is quite probably both: secretion, represented by the bile salts; while excretion is represented by the bile pigments, salts of iron, copper and magnesium, neutral fats, nucleo-proteins, phosphatides and cholesterol. Bilirubin and cholesterol are the two excretion products of special note in this connection, and furnish the keynote to this paper. Bilirubin is formed originally in the spleen through disintegration of the red blood corpuscles and the splitting-up of the hematin. It is transported to the liver and eliminated with the bile. It undergoes some further change in the intestine; some of it forming *urobilin*, a part of which normally is reabsorbed. If the liver be overtaxed, urobilin makes its appearance in the urine in undue amounts. Blocking of its excretory ducts results most quickly in impaired function. Again, if the bile flowing through the biliary ducts be acted upon by certain bacteria, one of the immediate results of such bacterial action is the formation of an excess of urobilin which, of course, must be eliminated by the kidneys. The practical point is this:

*Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

That the presence of an excess of urobilin in the urine is not only an index of impaired liver function but is also a strong indication of infection in the biliary ducts.

Cholesterol or cholesterin has been the subject of much recent investigation. First discovered in the bile, as its name indicates, it was supposed to be secreted by the mucosa of the gall bladder. It is a carbon-hydrogen-oxygen compound, a monatomic alcohol, a primary cell constituent and is doubtless a product of protein metabolism. Luden, of the Mayo Clinic, has made a long series of experiments to determine its importance in the economy and seems to have established a definite relationship between diet, blood cholesterol and the lymphoid defense. It is indicated, for example, that an excess of food rich in cholesterin, as the yolk of eggs, increases the cholesterol content of the blood but decreases the activity of the lymphocytes.

Now cholesterol is an excretion product in the bile and is held in solution by the bile salts and soaps. This solvent quality of the bile is reduced by changes in its mucin content induced by bacterial attack on the mucosa. With this result, viz., that the cholesterol is precipitated and a coagulum is formed containing cholesterin, mucous and bacteria, and, in some instances, bile pigments, calcium and magnesium salts. This is the genesis of gall stones, a complex of faulty metabolism and bacterial action. These reactions may take place in any part of the biliary tract, though of course most commonly in the gall bladder.

The point we are driving at is this—*that biliary infection is antecedent to cholelithiasis.* From this point of view gall stones are mere accidents in an important pathological process. They are by-products of bacterial action in the bile ducts; in other words, they occur in some cases of infective cholangitis. And if they occur more frequently in the gall bladder it is only because the gall bladder furnishes the conditions most favorable for bacterial growth.

Now the subject of gall stones has held the fancy of the surgeon since the time of Bobbs and the surgeon has dominated this field. The internist did not give it up, however, without a struggle. As late as 1890 we find one of the Professors of Medicine in the University College of London, advocating the diagnosis of gall stones by sounding with a trocar; and their removal, by manipulation of the abdominal wall. But surgery in the course of time has gone to seed on the question of gall stones, and now the situation is reversed. Without further argument we say simply that for a time at least we are going to relegate gall stones and to think in terms of cholesterinaemia and cholangitis, perhaps, even to the extent of developing a fad.

What bacteria are concerned in cholangitis and how do they gain an entrance to the bile ducts? First and foremost are those of the colon group.—the communis coli, the typhoid, the paratyphoid and related organisms. It might be expected, a priori, that these bacteria would be at home in a bile content since their habitat is the colon. Normally, but not constantly, they are found also in the duodenum and the ampulla of Vater. Gastro-duodenal catarrhs furnish favorable conditions for their invasion of the common duct and thence they spread to the radicals of the biliary system. With less frequency they are carried to the liver by the portal vein and under certain conditions of lowered resistance filter through it with the bile to gain eventually a foothold in the mucous lining of the bile tracts. In other cases, perhaps, their approach is by lymphatic paths. These bacilli are the most frequent cause of the milder types of cholangitis and are the most important factor in cholesterol precipitation and so of stone formation.

The staphylococcus does not seem of great importance in the etiology of biliary infections. It is more easily destroyed by the liver perhaps, or if it is of a virulent type, it is more likely to form small emboli and thus give rise to abscess formations in the liver substance.

The pneumoccocus does not seem capable of living in bile.

It is the *streptococcus* that gives us the most concern in this epoch. It seems that since the great grippe epidemic of the late eighties, the activities of the streptococcus have almost changed the character of infective disease. The grippe organism and the streptococcus are probably commensal or symbiotic, with their first predilection for the lymphoid tissues of which the tonsil and the appendix (especially in the young) are chiefly composed. From these coigns of vantage they sally forth for attack upon other tissues. Thus the tonsil may be the most frequent source of the infection which is such a large factor in gastric or duodenal ulcer, while the appendix, probably, more often infects the hepatic area. These infections frequently constitute in themselves a vicious circle—infecting and reinfecting—so that one who seeks to trace cause and effect loses himself in a bewildering maze.

The acute forms of streptococcus infection in the bile tracts produce the edemas and the gangrenes that present the most urgent symptoms. The more chronic forms give rise to fibrosis with a long chain of evil consequences —obliteration of the gall bladder or the ducts, distortions, changes in relation of the pylorus, etc., by reason of adhesions; and as secondary sequelae, serious disturbances of function in

the stomach, duodenum, colon and pancreas, not to speak of the multiplicity of remoter complications. And at any time these cocci may take on a hemolytic form. Many cases of supposed pernicious anemia or hematogenous jaundice are at bottom streptococcic infections in the biliary tract. In many such cases a tarry bile will be found in the gall bladder. Cultures from the bile may be negative but taken from the mucosa will be positive. In the milder types of infection the progress of the disease may be quite insidious. The most serious change may take place without the patient's suspecting. Hydrops of the gall bladder is a single example of such change.

The *practical application* of these observations is that it is imposed upon us to associate the idea of slight infective tissue change in the bile passages with functional change; to reconstruct our notions of all that the old term "biliousness" connotes; to devise a more alert symptomatology to the end that we may anticipate and prevent these serious surgical conditions. For in these cases surgery can never secure a complete and permanent restoration of function—*and these conditions are largely preventable.* Prophylaxis, then, constitutes the first line of defense, the underlying principles of which can be, at this time, only indirectly suggested in calling to mind the several factors that predispose to biliary infection. These predisposing factors are: (1) Errors of diet—those which excite gastro-duodenal congestion, those which afford a preponderance of a class of food substances—whether it be excess of proteid and cholesterol forming foods or an excess of fats, or those which keep the physiologic function at a constant high pitch. Diet in its relation to biliatian furnishes a large field for further clinical and laboratory experiment. (2) Pregnancy, which predisposes to biliary infection in several ways, bio-chemically and mechanically. In this connection we cite, for example, only one significant fact: In pregnancy the blood cholesterol is always greatly increased. (3) Foci of infection, a factor which might be evaluated in detail without end.

Diagnosis. With these known predispositions to suggest, and certain well defined groups of symptoms to point the way, one should seldom fail to reach a correct conclusion as to the presence and the nature of a biliary infection. Important special symptoms are referable to the brain, the stomach, the bowel, pains direct and referred, the skin changes, and so on. We spoke of "biliousness" which is a term not to be laughed at, for it suggests a definite clinical picture,—headache, impaired cerebration, gastric disturbance, muscular debility, slow pulse, lowered blood pressure, etc.—which are doubtless the expression of choline poisoning. Now if to these manifestations of functional disturbance we add the findings of persistent and patient examinations of the blood and excreta, we will seldom go far astray in the diagnosis of biliary infection even in its primary forms.

Primary changes in the ducts due to infection. There is a special reason why primary inflammations in the bile ducts—these earliest forms of cholangitis—have attracted comparatively little attention. The explanation lies in the fact that they are not apparent at necropsies,—the edemas and congestions having disappeared post mortem. The earlier tissue changes in the bile ducts due to infection, even in life, are not always apparent to the most practiced operating surgeon.

McCarty, of the Mayo Clinic, has recently described the microscopic changes and the order in which they probably occur. (1) Congestion and edema of the villi which are sometimes cystic. (2) Lymphocytic infiltration involving, gradually, the mucosa, the submucosa, the mucularis and subserosa. (3) Fibrosis involving all these layers. (4) The presence of large spheroidal cells filled with finely granular lipoid substances in the mucosa and submucosa. It is emphasized that these changes are not limited to the gall bladder and extrahepatic ducts, but are found in the ducts within the liver as well. These findings have extreme clinical significance and are worthy an hour's elaboration; the gross pathological changes, on the other hand, are so well known as to require no description.

Treatment of Biliary Infections. The treatment of biliary infections should first of all be prophylactic, the details of which are connotated in the enumeration of the predisposing factors which have been referred to. If prophylaxis has been lacking or ineffectual and infection is well developed, there is only one treatment of any avail, and that is *drainage.* The drainage may be *medical* or *surgical.*

In the acute catarrhal forms of cholangitis, medical drainage may be efficient and sufficient. By this is meant that measures are instituted to reduce the gastro-duodenal edema in order that the orifice of the common duct may regain its patency and a free flow of bile be established. To this end the digestive tract is emptied completely and kept so, in the meantime supporting the patient by rectal enemata —mostly saline.

In some cases the duodenal tube may be employed with the instillation of magnesium sulphate. Other adjuncts are useful insofar as they promote the one end, viz., to secure the free flow of bile. But medical drainage may be obviously a "pis aller"—going from bad to worse.

In the acute cases with indications of complete obstruction or of sepsis, and in the

chronic cases, it is indicated to drain surgically without delay. Ordinarily it is sufficient to drain through the gall bladder although in many cases it is necessary to place the drainage tube in the common duct or even extend it to a hepatic duct.

If a tube is left in the gall bladder only, it is imperative to be assured that the cystic duct is patent. If the common duct is permanently obstructed, plastic work will be necessitated, securing permanent drainage by anastomosis of the duct and duodenum, or of the gall bladder and duodenum, or even reconstructing the duct over a rubber tube.

External drainage should be encouraged until the bile is quite sterile and until the evidence that it escapes normally into the intestine is complete. The technique of drainage is too well established to require discussion.—the main points being to operate in such manner as not to spread infection and to prevent adhesions. In cases requiring simple tubal drainage the gall bladder should not be attached to the abdominal wall as was formerly the custom but it should be walled off from adjacent structures with rubber tissue. If, however, the mucosa is seriously impaired it will be better oftentimes to fix the gall bladder in the abdominal opening and drain with gauze. The chief difference of opinion at this time is as to the relative merits of cholecystotomy and cholecystectomy.

My own opinion is that the gall bladder should never be removed except for one cause, viz., permanent loss of function. In acute cases its function is permanently destroyed if its walls are gangrenous or edematous and thickened; in the chronic cases, if it is sclerosed. The problem is not so simple as that, of course, but it is not possible at this time to consider the functions of the gall bladder and the arguments pro and con *in re* removal. But this is certain, that the dictum that the gall bladder should be treated like the appendix has done incalculable harm, for it has encouraged the tyro who removes an appendix with passable grace to regard biliary surgery as a "get in quick, get out quick" affair, with its chief end to secure another surgical scalp in the shape of a gall bladder to hang out to air as an added proof of surgical prowess—a technique as erroneous as it is vicious. The immediate results, it is true, may be excellent but what happens more remotely—well, that is on the knees of the gods. Whatever the serious or even lamentable eventualities, the operator may complacently fold his arms and say: "There is nothing more to be done; I removed the gall bladder." The traumatism done to the hepatic or common ducts, or their wholly inadequate drainage, does not appear in the record. There is no surgery that calls for a higher class of surgical judgment, and no technique is in any degree efficient which does not include a thorough examination of the liver and its adnexa, the stomach, the adjacent portions of bowel and the pancreas.

And whatever one's technical skill and surgical judgment his work is not permanently effective unless supplemented by an *after treatment* which may need to extend over months or years, the purpose of which is to correct the patient's predispositions and the recurrence of his biliary infection in more aggravated forms.

I should like to restate my thesis in even simpler terms:

(1) The importance of hepatic function is being overlooked both in diagnosis and therapeusis.

(2) The question of gall stones and their surgical treatment has overshadowed allied problems to a serious extent.

(3) Gall stones are to be regarded merely as by-products and not the inevitable concomitants of cholangitis—of infective inflammation of the biliary passages.

(4) Our attention should be directed to the bacterial agencies of cholangitis, their foci and mode of attack.

(5) The most common infective agents are the colon bacilli and the streptococcus, each of which is capable of producing a syndrome: The colon bacilli more related to catarrhal processes with adventitious choielithiasis; while the streptococci give rise to the serious acute inflammations and in chronic forms the slowly destructive and sclerotic changes.

(6) The sole principle of surgical treatment of cholangitis is drainage, which includes removal of mechanical obstruction.

(7) Removal of the gall bladder should not be made a routine part of such drainage.

(8) Surgery of the biliary tracts calls for the highest degree of surgical judgment independent of technical skill.

DISCUSSION

DR. W. D. ASBURY (Terre Haute): It appears to me that the subject of biliary infection is one of the most important things with which we have to deal. It has happened often in the past that the surgeon has performed a cholecystectomy or a cholecystotomy and still has some of the same condition remaining, just as the removal of a gastric ulcer does not always remove the source of trouble. A study of the gall bladder and liver functions is a particularly interesting one from its embryological, physiological and anatomical standpoints.

To have a clear understanding of the stomach, the liver, the duodenum and the pancreas we should know of their embryology, anatomy

and physiology. These organs are all embryologically very closely related and for this reason it is very difficult to differentiate certain diseased processes of these organs. They all receive their nerve supply through the splanchic nerve. The peculiarly nice adjustment of the flow of bile in man has been brought about through the sphincter of Oddi and the ampulla of Vater, whereby when bile is needed the flow can be regulated according to gastric needs and the remainder can be stored until further needed. This continuous flow of bile in lower animals has been converted in man to a dis-continuous flow. If we leave out these fundamental facts we have left out the most important consideration. All medical treatment following these gall bladder operations should be rendered in the light of these above facts.

The subject of cholesteremia of the blood is especially important. Urinalyses are often made with the thought that one is analyzing things from the kidneys. Perhaps even the sugar and other excretory products found in the urine should be considered an output of the liver as well as the kidneys. When a child does not wish to eat the yolk of an egg, he probably knows more about it than the doctor who recommended it, for it increases the cholestoral of his blood. All treatment directed toward these biliary infections should be done with a clear understanding of the above facts.

DR. WILLIAM H. FOREMAN (Indianapolis): I wish to say that the seeming infections of the gall bladder are often not infections of the gall bladder. We have instances where the gall bladder has been drained and even where cholecystectomy has been performed, with the patient having the same symptoms that he had before, so we cannot attribute these symptoms to the gall bladder infection. These conditions may be due to stasis in the colon. As we know, there are no glandular secretions in the colon to prevent fermentation or decomposition of the food, so we have fermentation and decomposition occurring in the colon when there is retention, and which may give us the symptoms of "biliousness". So I believe many of these symptoms of so-called biliousness are not due to gall bladder but to colon conditions. However, it is my custom to make a blood count in such cases and if the blood does not show an increased leukocytosis I question whether we have a gall bladder infection. A leukocytosis very seldom occurs from fermentative changes in the colon but is usually present in acute gall bladder infections. I think a very careful blood count is necessary to know whether the patient should have the gall bladder drained, or whether his colon should be looked into and the condition corrected there.

DR. GEORGE W. MCCASKEY (Fort Wayne): The author rather incidentally mentioned studying the bile passages by the use of the duodenal tube according to the Meltzer-Lyon method. I have been very much interested in this subject and have made about one hundred observations on about forty patients. The contents of the gall bladder cannot be uniformly obtained and I prefer my clinical assistants to consider bile passage drainage instead of specifically gall bladder drainage which may or may not have been accomplished. It seems to be quite rational to procure the bile if we can, segregate that derived from different parts of the biliary tract if possible, and study it in every possible way, just the same as you would secretions from the stomach or urinary tract. I regard it as an extremely important addition to our methods, although its exact scope and limitations have not been determined. I will add, however, that in many instances I have been shown the segregated bile specimens, and have not the slightest doubt that the gall bladder has been at least partially emptied, and that in such cases it can be separately studied. In a number of cases we have been able to definitely prove the existence of pus, pathogenic germs, etc.

Although speaking with considerable reserve I will say that in at least a few cases very definite therapeutic results were apparently obtained.

DR. GEORGE W. SPOHN (Elkhart): The second discussant stated that in some instances we find a colonic infection. He did not give us the differential diagnosis as to when we have a colon and when a biliary infection, and I would also like to know what the treatment is if it is a colon infection.

DR. WILLIAM H. FOREMAN (Indianapolis): (Replying to Dr. Spohn). It would take a long time to answer Dr. Spohn's questions. One point I mentioned in the differential diagnosis is that if the blood count does not show a leukocytosis it is pretty evident we have no acute biliary infection. Of course, I realize we may have a chronic, low grade biliary infection and no change in the blood count. We have cases that have been operated with the gall bladder drained and sometimes the bilious symptoms persist just as before. That is not saying anything against surgery for I thoroughly believe in drainage of the gall bladder and cholecystectomy when indicated, but I say that we have cases in which this has been done and the same symptoms obtain, and then we must think of something else and usually in these cases the difficulty lies in the colon. I could answer the question as to treatment if I had time, for they can be treated and absolutely cleared up if it is a colon condition, but I have not the time to go into this now.

DIAGNOSTIC USES OF THE DUODENAL TUBE

G. W. McCASKEY, M.D.
FORT WAYNE, INDIANA

During the last decade the ever-widening clinical application of the duodenal tube has greatly increased our knowledge of gastro-intestinal disease by rendering the clinical data more available. To this has rather recently been added the diseases of the biliary apparatus. Though primarily intended for duodenal examination, it has, in my work, and I think in that of most other clinicians, entirely superseded the Ewald tube in gastric analysis. Its advantages are obvious. Perhaps the greatest of these is that because of its small size, softness and flexibility of construction, it can be tolerated for hours, or even days, permitting of many and frequent observations of gastro-intestinal chemistry, or even repeated therapeutic procedures.

Fractional Gastric Analysis. The old method of removing the test meal in one hour, and classifying the case according to the findings at that time, was based upon the false assumption that the crest of the acid secretion would then be reached. It would not have been practical in many cases to introduce the cumbersome Ewald tube more than once, and it therefore became necessary to select some uniform time for the procedure. We now know, however, that there are wide variations in the time of maximum secretions.

In the following table the findings in ten selected cases are given in relation to the free HCl content, during gastric digestion. The figures corresponding to a given case at a certain time represent "degrees" of HCl acidity, the standard being that 100 degrees represents decinormal HCl, which is equal to about .36 per cent.

HCL IN FRACTIONAL STUDIES

Case No.	1 hr.	1¼ hr.	1½ hr.	1¾ hr.	2 hrs.
1	36		35		0
2	0		0		15
3	0		12.5	15	
4	10		10		24
5	23	57	64		
6		28	50	76	52
7	20	31	40		
8		12	36	34	46
9		90	50	50	
10	0	0	0	0	

A glance at these cases will show how entirely unreliable would be any conclusion as to maximum secretions based on an analysis made at the expiration of one hour.

The curve of secretions in case "1" apparently conforms fairly well to the older work, the maximum free HCl contents probably being reached in about one hour, and disappearing in two hours. Cases "2" and "3" would have been classed as achlorhydrias, whereas they are really hypochlorhydrias. Cases "5" and "6", on a one-hour basis, are quite within normal range. As a matter of fact they are both definite hyperchlorhydrias. Case "7" begins fairly low, but ends rather high. Case "10" begins the same as "2" and "3", but remains consistently achlorhydric throughout, and case "9" is a definite hyperchlorhydria, with the maximum secretions, during the period of observations, at 1¼ hours.

There are of course other phases of gastric secretions, aside from the free HCl content, which can be "fractionally" studied in this way, but this shows better perhaps than any other single phase, the pathologic aspects of gastric secretions. It is probably more often perverted, and also, more than any other, offers valuable therapeutic suggestions.

These observations, taken more or less at random from my clinical records, are not designed so much to throw light on gastric secretions as to indicate the clinical applications of the duodenal tube in the study of gastric diseases.

We have analyzed two hundred recent consecutive cases, simply to determine in what proportion of cases the HCl secretion increases or diminishes after the first observation made at one or one and one-quarter hours.

Several interesting viewpoints were obtained in this analysis. Excluding the achlorhydrias, of which there were forty-six, or twenty-three percent, one hundred and sixteen, or about 75.3 percent, of the remaining one hundred and fifty-four cases showed an increased HCl content subsequent to the first observation. Again excluding the achlorhydrias, thirty-eight cases, or 24.7 percent, showed a greater HCl content at the first than at subsequent observations. Another interesting point is that seventeen cases would have been classified as achlorhydrias on the basis of the one-hour observation, whereas they all subsequently showed free HCl varying from 20 degrees up to 48 (1 case) and 55 (1 case).

The Study of the Fasting Gastric Contents. If the capsule of the tube is introduced into the fasting stomach, its contents can be studied chemically and microscopically. Information of decisive value may thus often be obtained. For instance the quantity of the fasting secretions may be very large (100 to 200 c.c.) or very small (1 to 3 c.c.). Normally I would say there is from 5 to 15 c.c. or possibly much more. The failure to get any is not necessarily pathologic. Chemically it may vary from an "achlorhydria" to an extreme "hyperchlorhydria", or give both the benzidine and guaiac reaction for occult blood. Microscopically, blood, pus and microorganisms may be recognized, and will have the usual significance.

Duodenal Secretions. Having studied the fasting gastric contents, the stomach is washed out and the tube allowed to remain in the situ. The patient then lies down on the right side and waits for the tube to pass through into the duodenum. This is the most unsatisfactory part of the entire procedure. Ordinarily it passes through in twenty to forty minutes, although it occasionally takes much longer. The determination of the location in the duodenum is not so simple as was at first supposed. Bile regurgitated into the stomach, an occurrence not at all rare, may easily give the false impression that the bulb has passed the pylorus. The reaction cannot be depended on because with regurgitated bile the gastric contents may vary from neutral or faintly alkaline to strongly acid. Substantially the same reactions may occur in the duodenum when acid secretions are poured into it from the stomach. We have found that the fluoroscope offers the only prompt, unequivocal proof, not only of the passage of the tube, which gives a peculiar, unmistakable curve to the latter, but also of its exact position in the duodenum. If, for instance, it has passed too far, it can easily be drawn back to the desired point under fluoroscopic observations.

The fasting duodenum always contains a certain amount of fluid, which may be a mixture of gastric and duodenal secretions, perhaps together with both pancreatic and biliary secretions. This fluid is aspirated and submitted to microscopic and chemical study. The microscopic findings are compared with those obtained from the gastric contents, revealing any additions which may have been made in the way of cells or bacteria. Chemically its reaction and also the degree of acidity or alkalinity is determined, although the latter will depend largely upon the character and quantity of the gastric secretions which have found their way into the duodenum. The enzymes contained in the duodenal secretions and mainly derived from the pancreas are carefully studied. These digestive enzymes are first the proteolytic, second the amylolytic and third the lypolytic. The stomach furnishes the proteolytic enzyme for gastric digestion and may contain the amylolytic enzymes derived from the ptyalim of the salivary glands. The activity of these enzymes contained in the duodenal contents has an important bearing on intestinal digestion and is tested out in an incubator, respectively, by egg albumen, starch and milk fat. Pancreatic disease, or at least impairment of the pancreatic function, can thus be determined and is obviously of the highest diagnostic importance.

Bile Drainage. We have remaining for clinical study with the aid of the duodenal tube, the bulb of which is now in the duodenum, the secretions of the biliary apparatus—a most important and rather recent addition to our clinical methods of research. Whether or not the bile passages are the site of infections is a clinical problem which could not heretofore have been attacked by any method feasible for ordinary clinical study. However, with the bulb of the duodenal tube close to the papilla of Vater, if bile is freely discharged from the common duct into the duodenum it can be readily aspirated for clinical study. It can then be examined microscopically for cells and microorganisms after the duodenal mucosa has been thoroughly cleansed in order to get rid, so far as possible, of any pre-existing material.

In order to secure bile in any considerable quantity, some sort of stimulation must be applied to the duodenal mucosa, without which secretion is either slight or absent. Normally this stimulus is supplied by the acid chyme which is expelled from the stomach when it has been prepared for intestinal digestion. This, of course, heralds the physiological demand of intestinal digestion for bile. In response to any such stimulation the activity of the liver cells is enormously increased, and large quantities of bile are poured directly into the duodenum. At the same time without any reasonable doubt, cystic bile in varying quantities, physiologically altered by the highly complex gall bladder mucosa, is added to the freshly secreted bile, doubtless for some important chemico-physiological purpose.

This is what I have seen happen scores of times from artificial stimulations, the precise nature of which does not appear to be very important; at least substantially identical results can be obtained with different solutions. Because of Meltzer's experimental observations with magnesium sulphate, later taken up clinically by Lyon, a 30 percent solution of this salt is generally used. Within a few minutes after the instillation of 30 to 50 c.c. of this solution, there occurs a free flow of golden yellow colored bile. There is usually 10 to 20 c.c. of this bile and then there follows from 30 to 100 c.c. or more dark colored bile, obtained in whole or in part from the gall bladder, this again to be followed by another flow of golden yellow bile, undoubtedly freshly derived directly from the liver cells. To question the clinical value of the chemical and microscopic study of these secretions would be tantamount to questioning the value of similar studies of the urine. The detailed discussion of the various findings would far exceed the intended scope of this paper, which is limited to a general consideration of the diagnostic uses of the duodenal tube. The writer has elsewhere* discussed these questions at some length with a considerable review of the literature. It may, however, be remarked

(*) "Non-Surgical Drainage of the Bile Passages," awaiting publication in the New York Medical Journal.

here in passing that the microscopical and cultural evidences of infections which may be thus obtained are of prime importance. It is quite possible to recognize these infections in the pre-surgical stage, and perhaps postpone or even entirely prevent the evolution of the latter. This would of course imply the possible prevention of gall stones—a late phenomenon of infection—and also gall bladder empyema. These are admittedly "consummations devoutly to be wished", and I believe in a certain proportion of cases entirely possible.

But perhaps of even greater importance is the bearing which these diagnostic studies, with their potential therapeutic applications, may possibly have upon the different hepatic pathologies classified under the conglomerate term, cirrhoses. No less noted a pathologist than Adami* believes that chronic infections, perhaps biliary, perhaps hematogenous, or perhaps both, play a conspicuous etiologic role in the development of these conditions. It would seem that the earliest possible recognition of these etiological factors might be found in the infections, the recognition of which is thus made possible by the duodenal tube.

Functional Liver Test. In 1913 Rowntree, Hurwitz and Bloomfield* offered a functional liver test which consisted of the intravenous injections of a measured quantity of phenoltetrachlorphthaline. The test as applied to man included the collection of feces over a period of forty-eight hours and the quantity of the dye determined by chemical and colorimetric methods. This method, because of evident drawbacks, was not clinically practical, and I, for one, never had the courage to attempt it in spite of the fact that along with all other clinicians I felt the pressing need of clinical data bearing on liver function.

Recently Aaron, Beck and Schneider† have proposed a modification of this test, in which the time of the appearance of the dye in the secreted bile is taken as the index of the function of the liver. As a matter of fact, this is quite analogous to the time of appearance of the phenolsulphonphthaline in the renal function test, entirely omitting all quantitative estimations, because as these authors observe, of the impossibility of determining the quantity of the dye which would inevitably escape down the intestinal tract. This method seemed to fit in so well with the methods we were already carrying out by duodenal intubation that we decided to try it out, when indicated in such cases, which we are now doing. According to these investigators the normal range or time of the dye to appear, after intravenous injection, is from fourteen to twenty minutes. They conclude that when the dye does not appear in the aspirated duodenal contents until twenty minutes the delay is sufficient to cast suspicion on the liver function, and that delays until thirty minutes or longer are definitely pathologic.

Summary. As an illustration of the amount of information which can be obtained from a single introduction of the duodenal tube, the following technique has recently been carried out in a few selected cases: The tube is swallowed in the fasting condition; the fasting gastric contents aspirated for clinical study, after which the stomach is thoroughly lavaged with normal saline, with or without the use of antiseptics. The tube is then allowed to pass on into the duodenum, and its exact position determined by the fluoroscope. The fasting duodenal contents are then aspirated for clinical study after which the duodenum, like the stomach, is thoroughly lavaged. The magnesium sulphate solution, or other stimulant selected, is then instilled into the duodenum and the bile, the secretions of which have been in this way augmented, is secured for suitable clinical study. At any time after the bile begins to flow, 1 c.c. of a sterile solution, containing 50 milligrams phenoltetrachlorphthaline is injected intravenously, and observations made at one or two minute intervals until the characteristic color reaction is produced when the bile is dropped into a 40 percent NaOH solution. After completion of the bile drainage and liver function test, a gruel test meal, made of cream of wheat or other fine material, is administered, the patient being required to take the gruel slowly, a mouthful at a time, in an effort to obtain insalvation. The progress of duodenal digestion of this test meal can be studied for from 45 minutes to one hour, after which the tube is withdrawn into the stomach and the usual fractional study of gastric digestion carried out.

It is therefore possible, in a case in which it is desirable, by the procedure above indicated, with a single introduction of the duodenal tube to get—

1st. The fasting stomach contents;

2nd. The fasting duodenal contents;

3rd. The secretions of the pancreas;

4th. The secretions of the liver;

5th. Make the functional phenoltetrachlorphthaline liver test.

6th. Make a fractional gastric analysis with the gruel test meal.

STATE MEDICINE*

CHARLES S. BOSENBURY, M.D.
SOUTH BEND, INDIANA

There never was a time when there were so many individuals and such a multitude of organizations with peculiar ideas and theories for the salvation of mankind. We are in a transitional state, aggravated and accentuated by the reaction from the war. We suffer from the Great Unrest. It affects every individual, crops out in every community. It has led to numerous proposals to correct evils, real and imagined. The path of least resistance has usually been followed so that the burdens would be lifted from the individual to the community, from the community to a larger governmental unit, from the state to the federal government. The numerous impractical, unnecessary, costly and elaborate suggestions and devices are often passed unnoticed, except by those who are personally interested in their becoming operative. This is the day of the propagandist, the professional uplifter and the busy-body booster. Among the many things they have tried to accomplish is to tear down what is good in medicine and substitute a system of State Medicine. This term is indefinite, but it is generally accepted to mean that the practice of medicine should be under the control, direction or subsidy of the state or national government.

Within certain limits the state should control the practice of medicine. It is necessary that the state license its physicians. It is also necessary to provide for the care of the insane, tuberculous and others who suffer from incurable maladies. It is right that the state maintain public health departments. It is right that the state should demand safety devices for workingmen, traffic and building regulations. And, difficult as the problem is, I believe it is nevertheless right that the state should attempt to control alcohol and venereal diseases. All these problems are general and require governmental control and regulation.

The problems of clinical medicine are individualistic, for, communicable diseases excepted, treatment is given for the benefit of an individual and not of the public. It is not generally accepted that public health departments provide treatment of non-communicable diseases or relief from physical defects.

In this country the rule is that when a person becomes ill he summons the physician of his choice, whose services he may continue or dispense with. The compensation the physician receives is determined by him and his patient. In other words the practice of medicine is purely a private matter so far as the patient is concerned and he is independent. He is usually able and willing to meet the necessary expenses incident to his illness and maintains his self-respect.

In order that we may study proposals for more economic and efficient care of the disabled, let us briefly consider the medical man from an economic standpoint. The increasing preliminary educational requirements, the added expense of medical training and the uncertain financial returns of medical practice have led to an actual decrease in the number of medical students and physicians who engage in private practice.

From 1904 to 1919 there was a decrease of medical students from 28,142 to 13,052, or a decrease of 53.6 percent, due chiefly to the fact that many medical colleges with low requirements were discontinued. Therefore, a number of prospective students not possessing the essential qualifications were unable to matriculate in the better schools. In passing, it may be pointed out that one reason for the existence of irregular medical cults is the fact that their devotees are able to assume the care of the sick and injured without the expense, effort or preliminary educational qualifications required of medical students, and the further fact that no matter how irregular or how incompetent they may be they are permitted to practice without interference of the state or the public.

There has been noticed the tendency in recent years for medical graduates and physicians who have engaged in practice independently to accept salaried positions with organizations of medical men or those requiring the services of physicians. There is, therefore, an actual reduction in the number of physicians who engage in independent practice. Also, equally noticeable is the tendency for trained nurses to accept employment with organizations. Attention has been called frequently to the inequality of distribution of physicians,—that is the abandonment of the rural districts for the more densely populated centers.

Then there is the development of specialism, the clinics, the diagnostic laboratories. Once more we see the drift away from the older order, —from the family physician and the individual physician. There is now more teamwork among physicians. This is manifested by recent attempts to standardize hospitals.

Medicine is in a transitional stage. From the standpoint of the patient are things going to be better or worse? From the standpoint of the profession, what is the outlook?

Every physician in private practice meets with three classes of patients, considered from their ability to pay for services rendered them. The first are the very poor who cannot help themselves. The second class are those who grade from the poor to the wealthy, those of the great middle class, from whom physicians chiefly derive their income. They are usually able to pay

(*) Read before the St. Joseph County Medical Society.

ordinary fees for services, except in cases where illness is long continued or accidents are very severe. The third class are the wealthy, from whom relatively larger fees may be obtained, but who in the aggregate contribute but a small part to the average physician's earnings.

It is frequently said that the poor and the wealthy may secure the best medical or surgical treatment and to a certain extent this is true. The poor are provided for in one way or another and the wealthy may command the services of anyone they desire. But this great middle class, the principal asset of the medical profession, the people who under ordinary circumstances desire competent treatment and who pay ordinary fees, do occasionally suffer from an injustice in our present system. It cannot be denied that there are extraordinary illnesses or accidents, with attendant economic losses, that at times prove most embarrassing.

Relief from these conditions is sought through charities, fraternal orders, poor relief laws, philanthropic organizations, voluntary insurance, mutual aid societies and the like. But the relief thus afforded is often but partial relief, for the financial returns to the disabled, when he is in need, are usually small and inadequate. The medical profession has not denied its duty towards the needy, and I doubt if anyone who is really in need suffers for want of competent medical attention.

Medicine as an art and as a science naturally undergoes evolution. There must of necessity be changes in methods of diagnosis and treatment to keep pace with scientific discoveries. And there must be adaptations and modifications in practice to meet ever-changing social conditions. Experience has shown that the medical profession has not lagged behind or hesitated to introduce anything which would aid in diagnosis or relieve suffering. Progressive physicians have been alert and studious, if not all leaders, at least capable of utilizing and applying new methods. The successful practitioner must always be a student and I submit the facts that medical publications have a large sale, that our postgraduate medical institutions are prosperous, and that our medical associations and societies are constantly diffusing knowledge, as evidence that the profession as a whole is endeavoring to keep informed and to improve itself at its own expense and effort for the benefit of the public.

Medicine has always been altruistic and now, as in times past, its devotees seek to meet changed social conditions. The problems of the sick and injured are within the province of the medical profession and not of the social reformers. If the history of medicine means anything it may not be amiss to suggest that physicians have and will continue to work out their problems, both scientific, and as far as possible, economic. But it must be insisted that if medicine is to progress it must not be embarrassed by needless restrictions and interference.

State medicine, in its broadest sense, would mean that there would be developed for all the people government hospitals and medical departments corresponding to those existing for the army and navy. All the sick and wounded would be taken care of at government expense, whether suffering from communicable diseases or not. All physicians and other personnel would be agents of the government, state or national. No serious attempt has as yet been made to go this far, but there have been numerous attempts to obtain state medicine in indirect ways, as by the introduction of various bills, particularly those providing for what is commonly called compulsory health insurance.

This came to us as German propaganda before we entered the war. Almost without warning, bills to provide state health insurance appeared in twenty-two legislatures in 1917. These were introduced at the request of the American Association for Labor Legislation, an organization whose membership lists show but few employers, workers or physicians, the three groups immediately affected.

This is the ambitious program these reformers have proposed:

"Health insurance should be required for all employees, to be paid for by employers and employees in equal proportion. The state should pay all costs of state administration as in the case of workingmen's compensation acts and all costs of supervision of insurance carriers. The benefits to workers under health insurance should consist of:

1. Cash payment of a part of the wages of workers disabled by sickness.
2. Complete medical care for the worker, including hospital and home care and all surgical attendance and the cost of all medicines and appliances.
3. Adequate provision for rehabilitation, both physical and vocational, in cooperation with existing public departments and institutions.
4. Dental care.
5. Medical care for the wives and dependents of the workers if the same can be done constitutionally, and a burial benefit for the worker."

These bills were introduced upon the plea that "there is no other measure now before the public which equals the power of health insurance towards social regeneration". In spite of nation-wide propaganda, not a single bill has been enacted into law. It may therefore seem out of place to discuss something which apparently has been settled. But there is no assurance that similar bills will not be introduced in the future because of the encouragement offered by the passage of the Shepard-Towner

bill, which provides national and state aid for expectant mothers and is intimately related to the bill for compulsory health insurance.

What are the objects of state health insurance? Primarily it would appear that its proponents have in mind equalizing or eliminating economic losses due to illness. It must be first shown that there is genuine need for such aid. It has not been proved that the economic loss from sickness is so great, embarrassing or urgent that an elaborate and costly system of state aid is required to offset it. Every physician knows that the major portion of his time is spent in caring for patients whose illness is short lived and does not incapacitate for work for many days.

An argument is that "a national emergency exists as regards the adequate health protection of our people". This assertion is based upon the findings of the draft boards, that one-third of the men examined were declined for military service. These findings are frequently quoted to prove the physical deterioration of the American people. It must be remembered that they were based upon antiquated military standards which were very strict with regard to certain physical defects, and which made a man undesirable for military duty but in no way affected his health or ability to earn a living. When you figure up the draft boards' findings from the standpoint of a health survey they will be toned down considerably when it is learned just what constituted physical defects, according to military standards.

Another argument is that such a system will "make complete medical care available to all wage earners, their wives and children and protect all wage-earners, including those who would otherwise lack the means or foresight to insure". In other words, the workingman will have to take no heed of the morrow, the state will care for him if he gets sick.

It is also asserted that health insurance would "tend to reduce lost time and labor turnover due to prolonged cases of sickness". Just the reverse has been found to be the case in Germany and England where malingering is an ever-growing blight on the workingman. It is believed that the cost would represent four percent of wages paid workingmen, based upon Germany's experience. There is no available information on this subject because German reports do not permit one to determine what percentage of the wages is used. But lately, in England, the rising cost of state insurance has led to decreasing physicians' fees rather than raising the workingmen's contributions. Reliable American students of this proposal estimate the percentage would be more nearly fifteen percent of the employee's wage.

Still another ideal of the reformers is the "hope to reduce the incidence of tuberculosis, feeble mindedness and venereal disease",—certainly most commendable but no information is forthcoming as to the methods to be employed in bringing about the desired reduction.

Whatever arguments may be advanced for compulsory health insurance we cannot lose sight of the origin of the system in Germany. It was political subterfuge. It was not an honest attempt to better the workingman but to control him. It was Bismarck who engineered the plan, which has as its object not health promotion but political domination. It was his solution of the problem of the growing socialistic movement in Germany. It was his means to destroy the Social Democratic Party, and this system has been the most drastic, burdensome and unnecessary means of social control conceivable. It has failed to check the spirit of socialism in Germany. It has failed to protect the health of the German workingman.

In 1911 Lloyd George succeeded in introducing health insurance into England. He has said: "It was from Germany that we who were privileged to be associated with the application of the principle to the United Kingdom found our first inspiration, and it is with her experience before us that we feel confident of the future." Mr. Lloyd George had had no experience which qualified him as an expert on public health and was easily misled and gave his endorsement of a measure which has proved as unsatisfactory in England as it has in Germany.

Compulsory health insurance is unjust to the public, to the workingman, to the employer and to the medical profession.

State health insurance is intended to apply only to workingmen, and, if it has its advantages, they are the advantages of a class as opposed to the public at large. It would not insure the health or care for the majority of the population. It would have no effect in preventing illness or accident. And, ultimately, the public would pay the bills, for the employer to cover his share of the expense would add it to the price of his products. It would, therefore, simply mean a shifting of funds, to which must be added the cost of the shifting, in the way of administrative expenses, that is increased taxes.

Compulsory health insurance is unfair to the workingman because it would compel him to become dependent, to lose his identity and become a card-indexed unit. It will be forced upon him, because he has not asked for it. Labor leaders have repeatedly expressed themselves against the measure. It will destroy the worker's domestic privacy, his self-reliance and self-respect, for he will be subjected to official and officious scrutiny of administrative officers. He will be deprived of five, ten or possibly fifteen percent of his earnings to create his share

of the funds necessary to carry on this insurance. He has no control of these funds. That is the state's business. The workingman must understand that only fifty percent of them will be returned to workers in the form of cash payments, medical services and funeral benefits, while the remainder will be taken from his control to provide for reserve and guarantee against the days of epidemics and catastrophes, but actually made available, under the bills proposed, for the creation of an army of lecturers, social surveyors, field inspectors and other administrative officers. These funds, running into big money, will trickle back to the workingman in tiny rivulets. Aside from financial considerations, the workingman must understand that while apparently he is getting something for nothing or for very little, he will be the one who most suffers. Experience has shown that medical men employed as insurance physicians will not and cannot do them justice because they are burdened by red-tape, limited as to the kind of medicines and surgical appliances which may be used, and overworked by the needless as well as the necessary demands upon their time.

This system is an injustice to the employer inasmuch as he is made responsible for forty percent of the cost of medical care of his employees but has absolutely no control over them in the matter of preventing illness. He cannot require periodic physical examinations nor insist upon corrective surgical operations when they become the controlling factor in health. He cannot enforce cleanliness nor any of the measures to prevent venereal disease. There is a difference between the employer's relation to his employees regarding accident. He is responsible for accidental injuries, not due to the employee's carelessness. It is necessary for him to reduce the accident hazards in his plant and to protect his employees in every way possible. He has some control over his employees, while they are at work. And, there is usually a definite relationship between an accident and resultant disability and the employer is rightly charged with the care and compensation of his injured employees. With the exception of occupational diseases, the employer is not responsible for the illness of his employees and their families, and cannot in justice be compelled to contribute to the support of compulsory health insurance.

Finally, compulsory health insurance is an injustice to the medical profession. It is all too clear what it would mean to the physicians of this state if our legislature should enact a law of this kind. What is the purpose of such a law? Apparently, among other things, to secure medical attention, and this includes dental attention, at reduced cost. If the cost is reduced, who makes the reduction? There is but one answer, the physicians and dentists, and perhaps the law would be interpreted to include the nurses. In England it applies to druggists as well, for there is a list of approved drugs, chosen mainly from the standpoint of cost. If physicians prescribe or druggists dispense drugs not approved they are liable to prosecution. In America it would be difficult to arbitrarily fix the price of drugs, surgical supplies or hospital service and it is apparent that the chief means by which the cost of medical care would be reduced must be in the return for professional services. But, if it can be shown that the public would be benefited, then the medical profession has no right to object to it. The principle, "The greatest good to the greatest number" must prevail. The burden of proof rests upon the proponents of health insurance. Neither the experience of Germany nor England in the operation of state insurance indicates that it is desirable or necessary to adopt it in America.

The Shepard-Towner bill was recently passed and signed by the President. This is a law which bears the trade-mark of the professional reformers. It provides for assistance to the states to help women by prenatal and postnatal care. The federal government is to give from its treasury to any state which accepts its provisions and allots a like sum of money for its purposes: the money to be spent by the state boards to be created, under the direction of the federal board, created by the law. The federal board has but one physician, the Surgeon General of the Public Health Service, as a member, a physician whose special domain is preventive medicine, not obstetrics or pediatrics. The other members are the Chief of the Children's Bureau and the United States Commissioner of Educations, both laymen.

The law provides for an initial expenditure of $1,480,000 by the United States government. The money is to be spent to promote the care of and provide instruction for women in maternity. It is not the intention to provide for actual care of women in confinement. None of the welfare workers will lose an hour's sleep on account of a delivery nor even present the newborn baby with a diaper. That is not the purpose of the law. It is specifically stated that no money shall be spent to build or rent any structure for any purpose nor pay any pension, gratuity or stipend to any mother. The purpose of the law is to provide instruction and if the several states accept its provisions it will be costly instruction, several million dollars worth, in fact. The money will be spent to employ welfare workers. And what will they tell the mothers? That will be determined by the lay board at Washington!

Going back a little into the history of the

bill, it may be recalled that this law is a propaganda law. It was urged by the women's journals. For months these publications carried stories of cases where mothers had been neglected, published statistics showing that this country stands seventeenth in regard to the mortality following confinement, showed that 300,000 babies die before they are a year old and in every way imaginable roused the sympathy and support of their readers. In other words these publications, aided and assisted by numerous women's organizations, created an enormous lobby and kept up a vigorous campaign to secure the passage of this law.

The bill is the work of professional propagandists and from a political standpoint a dangerous experiment. From a medical standpoint it is totally unnecessary, inasmuch as there are now ways and means of securing this instruction and state assistance is not imperative. And further, it will never be possible to rid pregnancy and confinement of some of its dangers and risks. It so happens that the wives of physicians, that trained nurses and women physicians who become mothers suffer from obstetrical accidents just the same as other women. There is no known way of making pregnancy and confinement one hundred percent safe. It is absolutely impossible to materially reduce mortality by a course of instruction. If here and there a woman needs assistance during pregnancy or needs to be supplied with expert care during confinement, then by all means let that be supplied by the community, not by the state or federal government.

The law contemplates needless interference in matters which are private and sacred and not proper for official investigation or inquiry. The proponents of this measure believe that our people have degenerated and cannot care for themselves, but must become wards of the state, that they must sacrifice their independence and individualism and, no longer self-reliant, be guided by some central authority.

The burden of the care of women in maternity and their infants rests upon the physicians of the state, who have been licensed by the state to practice medicine, surgery and obstetrics. It is therefore inconsistent for the state to qualify physicians to practice obstetrics and also authorize and employ a group of welfare workers, not trained as physicians or obstetricians, to instruct women in matters relating to maternity and thus nullify the medical practice law of the state.

No practical good can come from lay instructors who must ultimately advise competent medical attention, which information can be imparted without the elaborate and expensive system contemplated in this law.

Another species of governmental control of medical practice is the limitations and restrictions placed upon physicians in regard to the use of narcotics. The Harrison Narcotic Act became effective in 1915. At first every physician who prescribed or dispensed drugs included in the law was required to pay a license fee of $1.00 per year and later this was increased to $3.00. A tax is usually levied because of some benefit but the physician is not benefited by this law. It was passed to restrict the use of narcotic drugs by addicts. However, though the tax is unjust, it is not nearly as arduous as the keeping of records, inventories and other burdensome paper-work features of the law.

At the time this is written there is considerable agitation concerning the medicinal virtues of certain alcoholic beverages. One day they are medicines; the next all their medicinal virtues are wiped out by legislation. Wonderful alchemy! Questions affecting the public health are evidently not to be settled by medical men. Their advice is not sought. Two opposing forces line up in legislative halls and determine to make might right and not to decide scientific questions according to facts. This tendency on the part of those ill prepared to solve the problems of public health is an ever-growing menace.

We have considered the problem of the care of the sick and injured from an economic standpoint. We have attempted to show that the practice of medicine is undergoing changes from the old order. The influences at work within and without the medical profession have been reviewed. The whole question is not medical but economic.

Economically the health of the people is of paramount importance. Illness and accident must be prevented as far as possible. The sick and injured must be restored to health with as little economic loss as possible. Economically the medical man is entitled to a fair return upon his investment. How can this best be accomplished?

There are many discordant factors difficult to harmonize. With the confusion that now exists there can be no definite solution of the problem unless some of these factors are discarded. It appears that attempts to solve the problem upon a community, collective or socialistic basis must fail, for it does not concern the community as a whole, but relates to individuals as such. The average man is able to provide medical care for himself and his family. Laws cannot produce economic results. It is impossible to equalize or eliminate economic loss from illness. We must provide for exceptional cases by private or organized philanthropy. But we must emphasize and stress individual responsibility, thrift, the Golden Rule, honesty and self-reliance. And when these simple, easily understood, natural and possible virtues are properly emphasized, we will have no need for

imported, complicated, expensive, unnatural, undemocratic and impractical devices to care for our sick and injured. We do not need governmental control or aid. We do need to practice some of the simple, tried and proved principles that have so successfully guided us in the past. To quote Dr. Raymond Pearl: "We shall save a good deal of money and human energy if we first take the trouble to prove that what we are undertaking to do is in any degree likely to achieve any useful end."

AN OLD INDIANA BOOK ON MEDICINE

A BIT OF INDIANA MEDICAL HISTORY

J. N. HURTY, M.D.
INDIANAPOLIS, INDIANA

A writer, some time gone, has spoken warmly of "old books, old friends and old wine". The old medicine book of which I would write is interesting, but does not belong in the class with old friends and old wine. There is no charm, no literary fine quality in it to arouse feelings of intellectual pleasure, but truly it is interesting.

It was published in 1836, in James McCall's Herald Office at Columbus, Indiana. The paper is poor in texture, is tender and tears easily, and has grown yellow and brown, the effect of the tooth of brutal Time. Time too shows its effect upon the plain brown leather binding, although it is true leather and not a base imitation. The types are worn and the workmanship is poor.

The author announces himself upon the flyleaf of the book to be Dr. S. H. Selman, and the title chosen is "The Indian Guide to Health, or a Valuable Vegetable Medical Prescription for the Cure of All Disorders Incident to This Climate". Between this full title and the name of the author we find this: "Designed as a guide to families and young practitioners."

The "Introduction" (he does not say preface) begins with a sentence containing one hundred and twenty-one words. It is decidedly high sounding and carries a flavor of bitterness and protest. It reads: "In all ages of the world the Science of Medicine has engaged the particular attention of the most learned of every nation; and of late years the time and talents of eminent individuals have been employed in communicating to their fellow-men dissertations upon Domestic Medicine; for which they have been censured by a majority of the medical faculty, who, with the most effrontery, assert that, by so doing, 'Every man is made his own physician'; and the consequent result is, that a majority of those who pretend that they have made themselves acquainted with all diseases, and their proper remedies, have to resort to some other occupation to gain a livelihood, and the Science is thereby injured."

How completely this sentence proclaims the man. He announces in it that he is irregular, and without doubt he never saw the interior of even an eclectic college, not to speak of the chiropractic college at Fort Wayne.

Despite the long beginning sentence Dr. Selman closes his introduction without great extension. His ending sentence is—"The reader will find in the latter part of this work, a Materia Medica, which points out the 'simples' wherewith the divine Creator has, in his wisdom, planted our gardens, fields and woods for the healing of our infirmities." He doesn't venture upon a reason why the Creator visited the infirmities upon us.

Dr. Selman wastes no words in presenting what he has to tell but "goes to it" head on. His first information is in regard to Herpes. To show his style I produce his entire matter on this subject.

HERPES

"Herpes consists in an eruption of broad itchy spots dispersed here and there over the skin, of a whitish or red colour, which at length run into each other, discharge a thin serous fluid, and either form extensive excoriations or ulcers. After a certain time scurfy scales appear, which peal off, and leave the under surface red; the same appearances are, however, renewed in a successive series, till the disease is either cured, or goes off spontaneously, which is indeed rarely the case. Being a complaint confined to the skin, it seldom happens that the general health suffers any great change. Its causes may be referred to a want of cleanliness, a low diet, and a damp situation; but certain constitutions seem nevertheless particularly predisposed to herpetic eruptions. The best remedies for these eruptions are ointments; such as the oil of corncobs, pennyroyal, sparemint, etc. While using the ointments, use cooling medicines inwardly, such as senna, salts, etc. Bleeding is also necessary while using the ointments, let the diet be light, there is no difficulty in this case if proper care is taken."

He next tackles "Tinea, or Scalled Head." His description is very good and he suggests "It is propagated by contagion, either by using a comb with the matter from the head of a person laboring under it, or by putting on his hat or cap." His prescription is as follows: "The hair should be shaven off the head and covered with an ointment made of dogwood berries, and the flowers of mulberry, stewed together in sweet oil or hog's lard. This should be used every night and morning. The head should be frequently washed in castile soap and new milk, it also may be washed at times in copperas water. If the glands of the neck should become swelled, a small blister should be drawn on the back of the neck, and be kept a running a few

days. By pursuing this course there is no difficulty of performing a cure. Scalled Head is very unpleasant, and as the doctors of today now know of this cure from the past, the passing of the disease is imminent."

The short chapter on "Hemoptysis or Spitting of Blood" is noticeable in that he differentiates between it and pulmonary hemorrhage. Under spitting of blood he says in part:

HEMOPTYSIS, OR SPITTING OF BLOOD

"In hemoptysis there is a discharge of blood of a florid colour, and often frothy, from the mouth, brought up with more or less of coughing or hawking, and preceded usually by a saltish taste in the saliva, a sense of weight about the precordia, difficult respiration and a pain in some part of the thorax. It is readily to be distinguished from hematemesis, as in this last, the blood is usually thrown up in considerable quantities, is moreover of a dark colour, more gumous and mixed with the other contents of the stomach, and is unattended by any cough; whereas blood proceeding from the lungs is usually in small quantity, is of a fluid colour, fluid mixed with a little frothy mucus, and brought up by coughing. A spitting of blood arises most usually between the age of sixteen and twenty-five, and may be occasioned by any violent exertion, either in running, jumping, wrestling, singing, speaking loud, or blowing wind-instruments; as likewise by wounds, plethora, pneumonia, weak vessels, hectic fever, coughs, irregular living, excessive drinking, or the suppression of some accustomed discharge, such as the menstrual or hemorrhoidal. It may be occasioned by breathing air which is too much rarified to be able properly to expand the lungs. Persons in whom there is a faulty proportion either of the vessels of the lungs, or the capacity of the chest, being distinguished by a narrow thorax and prominent shoulders, or who are of a delicate make and sanguine temperament, or who have had previous affections of the same disease, seem much predisposed to this hemorrhage; but in these the complaint is often brought on by the concurrence of various occasional and exciting causes before mentioned. A spitting of blood is not, however, always to be considered as a primary disease. It is often only a symptom, and in some disorders, such as pleurisies, peripneumonies, and many fevers, often arises, and is the presage of a favorable termination, if only very slight. Sometimes it is preceded (as has already been observed) by a sense of weight and oppression at the chest, a dry tickling cough, some slight difficulty of breathing, and a hard jerking pulse. At other times it is ushered in with shiverings, coldness of the extremities, pains in the back and loins, flatulency, costiveness, and lassitude. The blood which is spit up is sometimes thin, and of a florid red colour, and at other times it is thick, and of a dark or blackish cast; nothing, however, can be inferred from this circumstance, but that the blood has lain a longer or shorter time in the chest before it was discharged.

"It seldom takes place to such a degree as to prove fatal at once; but when it does, the effusion is from some large vessel. The danger, therefore, will be in proportion as the discharge of blood comes from a large vessel or a small one, and as the quantity is profuse or trifling. When the disease proves fatal in consequence of the rupture of some large vessel, there is found on dissection a considerable quantity of clotted blood between the lungs and pleura, and there is usually more or less of an inflammatory appearance at the ruptured part. Where the disease terminates in pulmonary consumption, the same morbid appearances are to be met with as described under that particular head, etc. As the general symptoms of this complaint is laid before the reader, we shall in the next place proceed to the treatment of the same; The first thing necessary is to produce that regular action of the lungs that nature requires, this may be done by astringent medicines such as the following:—Take half an ounce of pulverized cinnamon bark, the same of gum kino, the same of cubebbs, add these articles together in one pint of alcohol, let it stand for three days, the patient should take of this a half a teaspoonful three times a day combined with honey, this course of treatment should be pursued for several days. The patient should also take, a teaspoonful of sweet oil every morning combined with two grains of loaf sugar and five drops of laudanum, the constant drink should be a weak solution of cream of tartar combined with small portion of sugar of lead, if the bowels are costive the patient should use the tincture of aloes, or a strong tea of peach tree leaves, should there be any fever bleeding will be also necessary. If the stomach appear weak and much debilitated, a few drops of elixir vitriol should be used in a little weak tody two or three times a day. A small pill of opium may at times be taken. The head should be frequently bathed in cold water. The diet should be very limited, etc. I have laid down a few prescriptions and if the patient attends to them strictly he may be relieved."

Dr. Selman was at times a close observer, but very frequently essential and even obvious facts were invisible to him. This certainly is not strange, for the same thing happens even in "this know it all day".

Our author gives a long chapter of twenty-two pages on "The Diseases of Pregnancy". His descriptions show he was not a poor observer, and had extended experience. He warns against taking cold and becoming constipated.

"Toothache," he gravely says, "is painful and irritating and is to be feared". He prescribes oil of cloves and other essential oils to relieve, but says nothing about extraction, and is, of course, silent about treatment and repair by filling with gold or other materials, for modern dentistry was in swaddling clothes in his day. He directs—"When peculiar longings arise in a state of pregnancy, they should always be gratified if possible, as women are apt to miscarry from the anxiety these occasion, when not indulged in them: but that the child in the uterus can be marked by any depraved appetite of the mother, be mutilated by any disagreeable object being presented to her, can not be admitted. All aberrations from the usual form ought to be ascribed to the irregular operation of the powers concerned in generation, and are not produced by the imagination of the mother". If Dr. Selman arrived at this conclusion from his own observations he is certainly entitled to credit, for in his day the general idea in medicine as well as among the laity was that acquired characters were inherited and that awful sights seen by a mother might mark her child.

Mr. George Pence, of Columbus, who discovered Selman's Guide, says: "The book is highly impractical in these days, for its prescriptions call for whiskey, French brandy and gin, and the distillery over on Haw Creek and the one at Tannehill's are not making full time as in 1836."

The classical chapter of the book is entitled "The Cramp Colic". His description is graphic, even startling. He says: "The cramp Colic cramps the stomach and draws the patient sometimes nearly double with violent pains all through the breast, and will roll through the bowels like goose eggs, and sometimes goes off with a lax, a discharge of wind up or down before the patient can get any ease." For the cramp colic our "yarb doctor" prescribes parched peas eaten freely, also a gill of dogwood berries boiled in a quart of water down to half a pint. He remarks "this is wonderful and so is a large burdoc leaf in a quart of water boiled down to a gill and drank".

Costly colic treatment for the present time would be the last prescription: "take a young shoat and cut it open in haste and obtain the gall and drink it." Of his last prescription he says: "But of all medicines I have ever used is garlic boiled in new milk, this often relieves the quickest of any remedy that I have ever tried."

This chapter is fittingly closed with a stanza of rhyme as follows:

"This disease is very bad,
And cramps the patient up;
And if a cure can't be had,
You'll soon be drawn enough."

Dr. Selman, after giving his remedies for toothache, ends this chapter with the following effusion:

"I am sure this will cure,
If properly applied;
It's not hard, for to endure,
It's been frequently tried."

Only a few chapters of this interesting book are adorned with poetry and one more quotation will seal in our minds the poetical sweep of this early medical writer. At the end of the chapter on Scrofula or King's Evil, over which he claims complete control, is found this:

"Afflicted patients with this disease,
Have often come to me for ease;
(Tho much distressed have been their case,
I have never failed in curing them.)
I have never failed in curing all,
Who to me have made a call."

It seems that only one edition of Selman's Indian Guide was ever published and the price is not given.

"THE PHYSICIAN"

HOW MAY HE GROW OLD GRACEFULLY?*

FRANK B. WYNN,
INDIANAPOLIS, INDIANA

In the evolution from infancy to old age, man passes through several distinct physiologic periods, each dominated to a large extent by rather characteristic mental or emotional traits. The instincts govern infancy in great measure. In childhood the imagination runs riot, the growing nerve centers not yet having acquired the faculty of properly analyzing and interpreting afferent impulses coming through the senses. Hence the imaginative desires call for fairy tales, the barbarous exploits of Indians, or pirates. Very different indeed, but just as distinctive, is the epoch of adolescence, when the over-weening sex-ego asserts itself. This is the heroic or castle-building period when the young swain writes in verse his adoration of the female counterpart who chances his way, craving the ecstacy which her praise will bring. Next comes the dynamic period of life when maturity pushes youth aside and says: "I'm a man. Give a real task to perform." These are great days when a man is in the making. Hope leads on whilst brawn and nerve do the work. So for better or for worse he strives while the slow oncoming years stingily reveal

(*) Last of a series of articles by Dr. Wynn which have appeared regularly in THE JOURNAL.

their rewards or failures. In a few years he strikes his gait, thence passing along the fastigium of his career conscious of power and influence, or lagging and discouraged because of failure. This is the long, work-a-day period which tells of triumphs or defeats. It should be the harvest time of life—material, mental and moral. Sudden rise to success in this period is apt to beget arrogance and conceit, harmful to subsequent progress. Better steady growth upon a carefully constructed foundation —a life of activity which mellows gradually into an attitude of stimulating and helpful reflection.

And now comes the last physiologic stage—the period of failure in power, mental and physical. At all events so frequently do these weakening physiologic activities appear, that the world by common consent has come to speak of old age as the period of senile decline. Must we needs accept senile decay as inevitable, unpreventable? As physicians have we not been entirely too prone to accept a stupid, irritable, and useless old age as an unavoidable misfortune calling for pity and forbearance? In passing along the gamut of life's changes should it not be possible so to shape our conduct that each period will attain its full fruition? Let our actions always be attuned to the consummation of a satisfying old age; not a thing to be dreaded, but a calm and serene sunset, glorious in its coloring, wise in its counsels, fine in its dignity. Who has not occasionally seen persons who have thus passed into a green old age? Have we not looked upon them and secretly hoped that such benign and hopeful serenity might settle upon our brows; that their steadfast faith and luminous hope might in like manner brighten our eyes as age dims the sweep of vision. Can we do aught to bring it to pass? This should constitute one of the finest aspects of far-seeing preventive medicine, so shaping the lives of men that toward the end, instead of inert gloom there should be freshness and fruitfulness. Not to all can such a happy consummation come, but their number might be multiplied a thousand-fold.

The purpose of the present discussion is more particularly to apply what has gone before to our own profession. Who has not observed again and again the physician who has spent an arduous and self-sacrificing life suffer in his old age the melancholic realization of diminishing business; heart-breakings because formerly devoted patrons are deserting him for the younger generation of practitioners; the embarrassing and saddening truth beginning to dawn upon him that the community will soon mark him as a "back number". Under the clouds of waning practice, powers and accumulating discouragement he is not able to envision new fields which he can cultivate. In truth so devoted has he been to professional labor that he is unfitted for anything else. All other forms of activity are strangers to him. In gloom he casts about for something to which he can lay his hand with interest and the consciousness of usefulness to the community.

The physician who would grow old gracefully must begin early. Throughout his career he is sowing seed which in his old age will mature as a repellant thorntree of cynicism and despondency or a tree which will bear the good fruit of contentment and usefulness. Very important indeed is it to acquire the right psychological attitude toward the whole problem of medicine. Whatever bent is pursued with vigor and tenacity can but exercise an important influence over the declining professional career. If the mastering passion is for "big business" and money getting to the exclusion of medical study, professional cooperation and genuine service to one's fellows, it may be sowing for a whirlwind at the close. The public, quick to acclaim the practitioner's business success, will be just as quick and quite unsympathetic in proclaiming a younger hero. Whether animated by mercenary motives or professional ambition the tendency is toward the same end. Quite a few operative surgeons belong in this group. In the long run they are apt to present a pathetic picture. Younger men come rapidly to the fore, in competition, writing papers and in other ways pushing for legitimate recognition and professional prestige. Capable and up-to-date or not, the senior practitioner will sooner or later find that he is losing his grip. He refuses to admit that the public is calling for younger men. With galling embarrassment he notes business going to others. He is very prone to become cynical and pessimistic. Such examples are not at all rare. Let the man who is in the midst of large practice remember that his day will soon pass. He should look forward to this change in his career with cheerful resignation, yielding to the younger generation with becoming grace. It will be better for his business but what is still more important it will contribute to his peace of mind.

Let not the argument just offered be construed as opposed to sound business principles. Industry and honest economic thrift in medical practice as elsewhere, constitute praiseworthy virtues. No weightier responsibility rests upon the shoulders of the active practitioner than the obligation to his own flesh and blood—the making of financial hay while the sun shines; the laying aside for a rainy day and old age. Besides frugality in habits this implies the keeping of orderly accounts, the charging of adequate compensation for services rendered, and the systematic collection of moneys due. It should

comprehend the carrying of sound life insurance—as family protection or as a safe investment. With a view to a permanent income during his declining years the far-seeing practitioner should early acquire the habit of putting aside definite amounts at regular intervals in conservative investments—preferably well chosen real estate, rather than those enterprises which fascinate with the prospect of large returns, but are attended by serious hazard. That medical men of high intelligence should occasionally be duped into the purchase of mining, gas or oil stocks would be ludicrous were it not so often disastrous to their hard-earned accumulations. Better a stable investment insuring certain if modest income than gamble for larger returns likely to prove a losing venture which will place upon old age a crown of thorns.

The cultivation of a habit of friendly cooperation with professional colleagues will prolong the fastigium of one's professional activities. There will arise less of the frictions, heart-burnings and disappointments which beget in advancing years a state of senile irritability, a sort of grouch against everything and everybody. In its stead will arise a bearing of good-fellowship and mental poise conducive to happiness, health and long life. But the finest rejuvenation for the aging physician comes from comradeship with young medical students and the younger generation of practitioners. How desirable, how important for each that there should be here a better understanding! On the one hand what harsh and irreverent conduct is that in a young man who cynically speaks of his senior colleague as a "moss-back"—heaping upon him ridicule and contempt because he fails to know some of the newer revelations of medical research and practice. How thoughtless and shortsighted in his reflections, for will not he some day be accounted a "back number"? Nor is a young man's ridicule any more to be excused than an old man's contempt. The point at issue is to emphasize that each should recognize the physiological transformations which take place. Both should be comrades sharing in the labor, the spirit and the cause of progressive medicine. True, the senior may not seek to do the technique of the laboratory or operating room, but he will be made younger and more alert by knowing about it. The junior member will learn from elder counsel the art of managing men, of understanding friendly service and psychological control, which look upon man as more than a machine. Such contact brings about reciprocity of the most elevating form—making the young wiser and putting into age the fire of youth and hope.

To grow old with equanimity requires patience, courage, charity for human shortcomings and abiding faith in one's fellows. With the period of old age nearing, we protest against its approach. Ostrich-like we hide our heads and try to make believe it is not the real thing. Thus coddling ourselves into the false view that we can do just as we used to, we fail in measuring up to our former standards, and of necessity fall below newer standards established. It were better to acknowledge that a different physiologic period has supervened and try to adapt ourselves to the obligations of a new order. In the early years of life we are expected to do childish things; but when we have crossed to the realm of full maturity we should put aside childish ways. Failure is the penalty if we do not obey this law of change.

Just as natural and real is the transition from the long and active fastigium of life's stresses to the quieter period of age decline. I protest against this always being classified as a retrogressive stage of human existence. True it may signify retrogressive and degenerative alterations in blood vessels and various organic structures; but let us not forget that progressive advancements are possible then in some of the finest mental and moral qualities of human accomplishment—the beautiful things of the spirit which may bless just as abundantly as any of the so-called practical qualities of active professional life.

The gradual transition from an active practice to what should be the more serene but not less useful period of advancing age means the giving up of many arduous duties and responsibilities. It is right and best that they should be surrendered to others. Let it be done without grudge or criticism. Sad to relate many physicians, and especially surgeons, seem incapable of doing this. They refuse to understand why patrons, once so devoted to them, are now turning to younger professional men. A higher conception of duty and even the practical philosophy of their own interest call for cheerful resignation to the changing physiologic conditions.

Equally important with giving up the old order is to be able to adapt one's self to the new of the declining age period. For years before, the far-seeing physician should have been evaluating his capacities with a view to preparing himself for efficiency in the old age period. Unfortunately most men, during the hey-day of professional activity, seem to consider that it is only necessary to put by funds for shelter, food and raiment; but is not the more important thing to plan to have something to *do* in declining years, which will satisfy the soul? The real man draws back at the thought of rusting or rotting. He would be a hero and die in the harness.

Resigned to give up active medical or surgical practice, the question is what may be

undertaken as a substitute to hold mental interest, arouse enthusiasm and give the consciousness of useful service? A brilliant light along the pathway of advancing age is always to be found in children. Happy should be the physician, therefore, who has children or grandchildren, with whom he may share comradeship—rejuvenating to him as it will be delightful and instructive to them. This is really nature's order—going back to the things which were a joy in early life. If children are not to be found in the family, then it should be the duty and pleasure of the aging physician to cultivate their companionship elsewhere. Abundant opportunities exist for the development of this rejuvenescence—in hospitals, orphan asylums, fresh air missions, schools, boy-scout organizations and the like. Frequent and wholesome contact of the right kind of elderly people with children constitutes the finest and most useful sort of social service—a type of psychologic training which cultivates reverence for old age, a thing too often neglected in our day when "Young America" is prone to shun the aged as crotchety and unsympathetic.

The cultivation of a habit of recreation is a duty which every physician owes to his patients as much as to himself. Rotation and variation in the stressful routine are just as necessary to his highest productive efficiency as rotation in crops is essential to fruitful production in the fields. Under a false conception of duty to patients too many allow exhausting activities to wear out their own mental soil. How necessary, therefore, the practice of wholesome recreation—the kind which rests, rebuilds, puts coloring and dynamics into the psychological realm of one's nature. Consideration of these matters in the proper season of life begets an enduring nervous constitution which functions with vigor and interest far beyond the accustomed span of years. Recalling those in the profession who have profited by this recreational philosophy, memory pictures some of the finest types of physicians who in their declining years have gone in pursuit of the finny tribe—ambling along mountain brooks in search of the shy trout, or gliding over lake in quest of the furtive bass or the gamey muskellunge. Who has not frequently seen the aged physician of this type, fresh from an excursion into the open; his youth renewed, his eyes glistening with delight as he recounts the experiences of his outing. But if one would reap the benefits of such wholesome sport in old age, he must develop the skill and love of angling early in his career.

For the busy practitioner's annual vacation, no form of recreation is more popular than travel. Physicians are excellent travelers. Aboard ship or on a great transcontinental train where the force of circumstances throws people together and brings to pass oftentimes the most delightful acquaintanceship, it generally transpires that a physician will be found in the group. Furthermore he is very likely to be reckoned a favorite in the party. His life-long mixing with all classes has trained him how to meet people and situations. His powers of observation have been made acute so that nothing of unusual interest escapes his attention.

Upon matters of scientific bearing his opinion is likely to be sought. He understands the laws of practical psychology and comradeship. His intelligence and adaptability make him a favorite. On his own part travel is most enjoyable. He can cheerfully accept disagreeable situations, turning misfortune into comedy—a rare gift.

Finally the physician as a traveler brings to his home environment the benefits of his sojourn abroad. He is eager to apply the knowledge gained to community improvement, whether it be in educational methods and equipment, improved streets, adequate and artistic public buildings, park development, playgrounds for children, more beautiful trees, flowers or comprehensive city planning. It has always been a matter of extreme pride to me how frequently physicians who have seen the world, exhibit the capacity and disposition to apply the knowledge thus gained for municipal or community betterment. It is a fine exemplification not only of good citizenship but of the wise application of principles which will be conducive to happiness and longevity.

Of the recreations regularly available for city practitioners, golf is perhaps the most popular. It fulfills the requirement of good hygiene, excellent sport, and delightful companionship. Age makes no distinction as to its votaries. It is worthy of remark what a large number of older men, even those of advanced age, become quite enthusiastic over the sport. Physicians should acquire the golf habit early as preparatory to the spirit and freshness which it will add to declining years.

Agriculture, horticulture or floriculture as business enterprises are not advisable for physicians retiring from active practice. At any rate to carry large undertakings of this character to successful issue will exhaust rather than rebuild and prolong life. On the other hand if they are entered upon in a small way, as recreative pursuits and not as business enterprises, they are commendable.

This thought suggests nature study as a recreative and rejuvenating activity for elderly physicians. Wherever in America the research student of history goes he will find the physician was a pioneer of fundamental scientific teaching in the community. In the offices of the doctors of the old school who still linger to bless their respective communities, there will often be found a collection of archeological or

geological specimens, some of them surprisingly complete. In the earlier days long journeys on horseback through virgin forests, over rugged hills and along stony creeks gave ample time for meditation and observation. An interest in natural phenomena was forced upon the physician. He became the authority upon trees, plants, wild flowers, and fossils; on the habits of bees, bugs, birds and animals. I would make earnest appeal for a revival of interest among physicians for nature-study; first of all for its hygienic, and instructional value throughout one's career, but especially for its beneficent influence in bringing to pass a green old age.

Sudden transformations frequently take place in the inorganic world, as earthquakes, storms, flood and fire. But where life processes go on, the method is imperceptibly slow. Particularly if the vocational energies have been for long very intense, nature protests against sudden cessation. For example if the athlete or prize fighter, trained to the limit, suddenly halts in his activities, he becomes rapidly soft and is quite prone to degenerative weakening. Similarly I have seen the hard working farmer at sixty, sell his land, move to town, begin a period of idleness, over-eating and under-exercising, and start rapidly down the disease toboggan, developing arteriosclerosis, hypertension, chronic cardio-renal disease with their multiplying sequellæ.

As in the case of physical pursuits, so in the mental realm, sound physiology counsels against sudden cessation. How shall we apply the same principles to the practice of medicine? Not a few practitioners who have pursued an intensive career up to the sixth decade, and have laid by a competence for the rainy day and old age, suddenly abandon medical work. With conscious pride they announce to the world that they have earned the right to ease and rest. Instead of the coveted relaxation and contentment, restlessness and dissatisfaction drive tension up. If according to one's scheme, medicine is to be completely abandoned (and such a course is often advisable), then plans must be carefully devised to occupy interest, give the consciousness of usefulness, and afford a certain amount of physical activity as well.

The physician's training and association with all classes and conditions of men fits him for understanding their psychology—their virtues, weaknesses. His knowledge of biology, hygiene and sanitary science prepare him in an unusual way to grapple with civic and public health problems and enables him to advise wisely in their solution. Naturally and logically therefore he should and does often fall into positions of public trust. Frequently it should be the duty and pleasure of the physician, during the terminal phase of his career, to serve upon Boards or Commissions concerned with Public Health, Education, Park Development, Recreation, Civic Improvement, Charity, etc. Such work constitutes one of the finest and most serviceable forms of activity in which he may engage. I have known several such who have rendered a conspicuous public service, incidentally honoring the profession. The inclination of some men to enter politics after retirement from practice is rather a dangerous experiment, for the uncertainties, irregularities and intensities are almost as harassing as professional work.

Every physician should cultivate early the habit of good reading, literary as well as medical; less of the daily, sensational trash and more of standard literature; always the best and most recent medical books and periodicals. During the period of active professional life good reading is a necessity if one would keep pace with progress. Its benefits never cease. For those who have passed the biblical allotment of years, what a storehouse of pleasure and companionship is found in good books! They offer the geniality of old friends and the interest of new ones. They keep the faculties burnished when otherwise they would rust. Thus from retained freshness and accumulating knowledge such physicians radiate a helpful influence everywhere. To children and youth they become inspiring companions. Reciprocally they receive from the young a benignant and life-lengthening tonic. These are physicians who learn the art of growing old gracefully.

Very fallacious is the view too generally entertained, that physicians in the terminal decades of life should neither study nor write. Let the senior practitioners of medicine awaken to their serious duties and responsibilities toward the profession. More particularly would I urge the obligation to history. The foundations of all future progress are laid upon history. Medico-historical research is an inexcusably neglected field. Let not those who take vain pride in doing a large practice flatter themselves that future generations in medicine will care much for this fact. In truth the future is more likely to give its meed of praise to the man who in his declining years records with faithfulness the story of prevailing epidemics; describes the course of public health movements, the rise and decline of isms and cults, and the medical fashions of the day; narrates incidents of medical sacrifice and heroism and carefully prepares the biographies of medical men who have lived in the region; collects, preserves, and describes medical relics.

Illustrating the appeal here made, Indiana has produced a striking example in the person of G. W. H. Kemper of Muncie. However fine may have been his career as general practitioner and obstetrician for fifty years, this service has not equaled in value to the profession the labor he performed after seventy, delving into the

life history of almost every doctor who has practiced in Indiana. What interminable patience it required but what a splendid reward in the gratitude of the profession and the beautiful volume produced. His example is worthy of general emulation. Are not the worth-while achievements and heroic deeds of medical men as much entitled to historic record as the lives of the captains of industry, the princes of wealth, the idols of shifting political life or the heroes of battle?

Behold how great is the reward of the faithful in medicine! The cup of the well-rounded physician's life is full to the brim with precious memories of friends. His acts of sacrifice and heroic devotion are glorified by the gratitude of aching hearts, and in the brightness brought to downcast eyes. Perchance his labor may have revealed some new scientific truth, or devised a better method of treating disease. Let the stream of his life flow on, bearing upon its current the buoyant craft of human service until it floats into the sea of eternity. Thus in the journey toward life's end, his paths will be those of peace and his rewards those of the just. As the prophet of old spake, so will it be said of him today: "The skill of the physician shall lift up his head and in the sight of great men he shall be praised." (Ecclesiasticus xxxviii:3).

THE END

CHAULMOOGRA OIL IN TREATMENT OF TUBERCULOUS LARYNGITIS

This report by R. M. Lukens, Philadelphia (*Journal A. M. A.*, Jan. 28, 1922), gives the results of sixty cases of tuberculous laryngitis treated over a period of eight months with chaulmoogra oil. The treatment was conducted more for the purpose of learning the effects on the pathologic lesions of the larynx and the symptoms than on the tubercle bacillus itself. Chaulmoogra oil gave promising results from the beginning in cases in which there were dysphagia and pain in the throat. In the majority of cases it exerted an analgesic action on the larynx, which became more complete after repeated treatments. While improvement in the lesions is slower than was hoped for, yet cases treated with chaulmoogra oil have responded as rapidly as those treated with other drugs, and the treatment is much more easily borne. Preilminary cocainization has not been necessary, and there has been no pain or discomfort in the throat afterward, but rather a pleasing sensation of warmth in the throat and chest. In the cases in which intratracheal injections were made, sputum was rendered more fluid and was expelled with greater ease. Dryness of the throat, which frequently is present in tuberculous laryngitis, was improved but slightly in the majority of cases. At first the oil was applied by means of a cotton tipped applicator saturated with a 10 percent solution in liquid petrolatum directly to the laryngeal surface. Later the strength was increased rapidly up to the pure drug. Chaulmoogra oil works best by intratracheal and intralaryngeal injection. One cubic centimeter of the oil, of the strength desired, usually 10 or 20 percent, in liquid petrolatum or olive oil, is drawn up in a Luer syringe armed with a metal eustachian catheter. While the patient holds the tip of the tongue, wrapped in a paper napkin, between the index finger and the thumb of the right hand, the syringe tip is introduced, guided by the throat mirror, into the pharynx (not the larynx) above and behind the epiglottis, care being taken not to touch any portion of the mouth or throat. Two-thirds of the contents of the syringe is discharged, drop by drop, into the trachea while the patient breathes quietly. The remainder is then dropped on the cords while the patient phonates. In this way, cough following injection is very slight and often absent. When present, it occurs within five minutes after the injection and lasts for a minute or two.

DELETERIOUS EFFECT OF BLOOD TRANSFUSION

It is stated by Lester J. Unger, New York (*Journal A. M. A.*, Dec. 31, 1921), that biologic tests demonstrate that the transfusion of whole, unmodified blood is of far greater value than that of citrated blood. Sodium citrate, even in the low percentage employed in a citrate transfusion, affects the red blood cells, rendering them more fragile. The value of such blood to a patient suffering from a hemolytic disease, such as pernicious anemia, is lessened to that extent. Sodium citrate diminishes the available quantity of complement in two ways: by its direct action on complement itself and by introducing into plasma an anticomplementary substance which fixes complement. This substance is obtained directly from the bodies of red blood cells. Sodium citrate also reduces almost to nil the function of opsonins, and practically destroys the phagocytic power of white blood cells. Furthermore, the phagocytic index of the blood of various donors differs. Since complement and the phagocytic power are of prime importance in the protective action against pathogenic organisms, whole unmodified blood from a donor with high phagocytic index should be employed when attempting to combat local or general infections by means of transfusion. In selecting a donor, attention should be paid to the finer qualitative differences in the blood.

VACCINES IN WHOOPING COUGH

In a recent article Appel and Bloom of New York City have given an excellent resume of the work done in the treatment of pertussis with vaccines. For some thirteen years the discussion has gone on—more or less half-heartedly through lack of sufficient enthusiasm on the part of its protagonists rather than because of any opposition. Briefly their position is this—that the use of a vaccine is logical because of the infectious character of the disease and because it produces a low grade toxemia; that its value is greater the earlier it is used and that it should be a mixed vaccine since the bacillus pertussis is always accompanied by secondary invaders. They recommend a vaccine containing per cubic centimeter

Bacillus pertussis	1,000,000,000
M. Catarrhalis	200,000,000
Staph. Aureus	200,000,000
Staph. Albus	200,000,000
Streptococcus	200,000,000
Bacillus Influenzæ	400,000,000
Pneumococcus I	50,000,000
Pneumococcus II	50,000,000
Pneumococcus III	50,000,000
Pneumococcus IV	50,000,000

The dosage advised was ½, 1½ and 2 c.c. given intramuscularly every other day.

Study of the statistics quoted as well as their own results justify their support of this form of therapy. As they suggest, its value particularly as a prophylactic must not be lost sight of merely because it is not 100 percent efficient. If as results seem to indicate the average duration of the disease is reduced to 30 days, its severity mitigated, the number of complications reduced and the mortality lessened, the use of vaccine therapy, at least as an adjunct to other methods of treatment, needs no further recommendation.

PATERNALISTIC MEDICINE

At the present time the medical profession is confronted with some very grave problems upon the solution of which depends the very life of the profession. It is unfortunate that various forms of socialistic, paternalistic or communistic medicine have been proposed by some of the leaders of our profession, and it is equally lamentable that these propositions have been supported in a perfectly innocent way by a few members of the medical profession who have not analyzed the situation sufficiently to appreciate the dangers that threaten if we adopt such a policy as proposed. In short we are not only heading toward bureaucratic medicine, but we are heading toward the extinction of the medical profession as a profession and the abolition of private practice. We appreciate the fact that some easy going individuals consider this an alarmist statement, but such is not the case. Already we are adding to the functions of federal, state and municipal agencies which have to do with the recognition and treatment of disease conditions, always widening the scope of the work and increasing the activities so that they encroach upon the private practitioner of medicine. Along with this we see our hospitals and institutions of learning encroaching upon the private practice of medicine through our free clinics, and their newest activity—the community clinic—separated from but under the control of these institutions. All of this means but one thing and that is a drift toward state medicine, a term as used by us meaning the practice of medicine in any of its phases under the patronage and control of federal, state or municipal authorities and in direct competition with the private practice of medicine. Some may say, "Well, what of it? Wouldn't it be better to have our sick and disabled population under medical care and treatment by the state with its abundance of capital and resources than under private service with all of its limitations?" To this we answer emphatically, "No!" Practically every activity of the government, whether federal, state or municipal, is the football of politics. The practice of medicine would meet no better fate. It would functionate first, last and all the time through political preferment, and political preferment never has and never will depend upon capability or efficiency, but depends upon expediency. The regular medical profession as it exists today, with its long record of scientific advancement and wonderful achievements in the recognition and cure of disease, would have little voice in shaping the policies of medical service under state control, for the pseudo-medical cults and all of their followers, including the ignorant and gullible, would not only far outnumber us and bring more political pressure to bear but they really would be more active politically than we ever have been or could ever hope to be in view of the natural repugnance we have for political activity. It is bad enough to have our governmental agencies so frequently in the hands of incompetents, but it would be still worse to

place the lives and health of our citizens into such hands, and that is exactly what would happen if the practice of medicine was placed under state control and thus made the football of politics. We have been quite content to support state medicine which has to do with public health matters as controlled and regulated up to the present time, but we are unalterably opposed to the widening of the scope of this work so that it includes any and all phases of the practice of medicine, as we also are opposed to lay domination of or dictation concerning the management of our hospitals, teaching institutions, clinics, or any phase of medical practice.

NATIONAL HOSPITAL DAY

May 12 has been designated as National Hospital Day, and hospitals all over the United States and Canada, and even England and Australia, are planning to observe the day with programs of various sorts.

Last year about 1,500 hospitals in the United States and Canada observed the first annual Hospital Day, and aside from educating the public regarding hospitals and all phases of hospital service, it is reported that as a direct result, many applicants for the nurses' training schools and many donations of supplies, equipment, and money were received.

The success of this project last year is an inspiration to greater effort this year. Dr. George F. Keiper of Lafayette has been appointed chairman of the National Hospital Day project for Indiana, and it is hoped that every hospital in the state will cooperate and make Indiana 100 percent in the observance of the day. Some suggestions for a program for the day are given herewith: Open house for the inspection of the institution and nurses' home; graduation exercises for nurses; exhibition by x-ray, dietary, laboratory, occupational therapy, social service, and other departments; serving of luncheons to clubs, business men and similar groups; luncheon for public, for which charge is made; distribution of literature and buttons; pageants by nurses, or by children under the direction of some local organization; baby show for infants born in hospital during past two years. Tactful guides should be provided to take visitors through the buildings. Pamphlets describing the various services rendered by the hospital, and giving some facts concerning its work, might be distributed. Special emphasis should be given to the value of nursing as a profession. A general meeting, addressed by some prominent medical or lay man might be planned for the evening, and if the nurses of the institution have a chorus, glee club or orchestra same could be used to advantage. Socially prominent trustees or members of women's auxiliaries might arrange a ball, the proceeds of which could be devoted to some special work of the hospital. Publicity is a most important factor. Endorsement should be received from the governor of the state, mayor of the city, American Legion, etc., etc., and publicity may be distributed by churches, schools, fraternal organizations, theaters, business organizations, and, last but not least, the press.

Information or advice may be obtained by writing to Dr. George F. Keiper, Lafayette, Indiana, state chairman, or Matthew O. Foley, executive secretary, 537 S. Dearborn Street, Chicago.

MEDICAL POLITICS

It seems strange that almost without exception the members of the regular medical profession overlook the effect of politics in attaining anything for the common good. They do profess to be interested in regulating the practice of medicine, in increasing the standards of medical education, and promoting everything that has to do with public health and sanitation. However, whenever proposed legislation concerning any of these matters is introduced in congress or in any of our state legislatures, how many doctors show any interest in the pending legislation by using their influence in behalf of the legislation or in breaking down opposition? On the other hand, the pseudo-medical cults, including the chiropractors, Christian Scientists, and all other opponents of regular medicine, put up a united front in opposition to every bit of legislation that offers hope of improving public health, medical education and standards for the practice of medicine, or anything else that has to do either directly or remotely with the prevention and cure of disease. It is freely remarked by senators and representatives in congress that a bill having the slightest reference to medical affairs calls forth hundreds and even thousands of telegrams and personal letters from members of the pseudo-medical cults, and scarcely no attention from members of the regular medical profession. Not only do these pseudo-medical cults use their own influence but they get their friends and acquaintances interested to the end that our legislators either in Washington or at the state capitols are led to believe that the sentiment so freely expressed constitutes the prevailing sentiment among constituents, and it is easy to vote that way, irrespective of what the private opinion of the legislator may be. As an instance of this activity, we call attention to the public health bill introduced in congress by Senator Watson, which should have the support of members of the regular medical profession. So far as we can see, the bill has no objectionable features, but it does provide for the appointment of a few medical officers as permanent members of the Public Health Service, and probably some of the pseudo-medical cults would like to feed

at the public crib so they are vigorously opposing the bill and making their sentiments felt by hundreds of telegrams and letters to Senator Watson from Indiana alone. In the meantime less than a dozen members of the regular medical profession of Indiana have written Senator Watson concerning this bill. As has been stated by legislators on more than one occasion, it is difficult to secure much needed medical legislation when doctors are so apathetic concerning it, and so seldom show enough interest even to take the trouble to write or telegraph their legislators concerning their attitude. It is both disappointing and discouraging, and yet doctors howl the loudest because such legislation is not effected. To use an advertising slogan, "There's a reason."

"FAIR PLAY TO THE PUBLIC"

An editorial in a recent issue of the New York *Evening World* commented on an investigation that had been made in New York in an attempt to test the quality of "chiropractic" knowledge. Normal individuals went to certain chiropractors, gave fake symptoms, and the chiropractors "discovered" subluxations whose presence defied the roentgen ray. The *Evening World* very properly pointed out that, possibly, if normal individuals went to reputable medical practitioners and reported fake symptoms, physicians themselves might "fall down" on both diagnosis and treatment. As a result of this comment, the *Evening World* received a number of letters of approbation from the chiropractors, in one of which the writer commended what he termed the paper's "policy of fair play to the chiropractors". The *Evening World* came back with an editorial whose title we reproduce in the caption. This editorial contains so much sound sense that we make no apology for reprinting it practically in full:

The *Evening World* is vastly more interested in a policy of fair play to the public.

Fair play to the public would, we believe, eliminate 90 percent or more of the present practitioners of chiropractic.

Fair play to the public would require adequate education of chiropractors—for example, a regular medical course plus the specialized postgraduate work expected of a specialist in other fields of medicine.

In such a course many would-be chiropractors would come to the conclusion that manipulation of vertebræ is not a cure-all, whatever its possibilities.

Fair play to the public demands that chiropractic processes should be used only by men who know thoroughly what they are doing and why. Both common sense and science deny that all ills are traceable to the spine.

Fair play to the public demands a strict curb on a great mass of quackery masquerading under the name of chiropractic. Fair play to the public would send a substantial percentage of chiropractors either to school or to jail.

Adequate education might develop some competent healers of a limited group of diseases from the crowd of incompetent meddlers. But, given education, it is probable most of them would cease to be chiropractors.

Jour. A. M. A., April 1, 1922.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

CERTAINLY there are grave problems confronting the medical profession today and they have to do with the very life of the profession. That these matters may come up for discussion at St. Louis seems very probable, and it is hoped that a constructive program will be adopted.

SOME rare bargains in instruments or surgical supplies oftentimes are offered in our advertising pages, to say nothing of announcements that are of interest to members of the medical profession. Probably our readers do scan the advertising pages but if not it will pay them to do so.

ACCORDING to the United States Census there have been very few deaths from smallpox in recent years, and the Census Department attributes this decrease to vaccination. In evidence of this, it is pointed out that the unvaccinated population is the one that suffers most from smallpox. Just how the antivaccination society is going to get around these government statistics is a question, but probably in answering they will use the slogan started by *The Journal of the A. M. A.*, "Figures don't lie, but figurers do".

How many medical men are going to exert their influence at the primaries in having suitable candidates for the legislature selected? How many medical men realize that only a little work in the selection of candidates does away with the necessity of a whole lot of work later on in the legislature in trying to offset the pernicious influence of legislators who never should have been permitted to come up for election? This is a matter for serious consideration, but

with the characteristic indifference of medical men we doubt if it will receive a second thought.

OUR State Association has a substantial bank account and is able to provide funds for any enterprise that is of direct value to the medical profession of the State. We are interested in wise medical legislation for the protection of the public as well as for the general advancement of medical science, and the Association has made provisions for funds that can be used in securing such legislation. Why wait until the legislature convenes before using some of that money? Why not begin the political work at the primaries or even before that? A dollar spent in political work sixty days ago would be worth one hundred and perhaps a thousand dollars when the legislature is in session. "Penny wise and pound foolish" certainly applies to politics as well as anything else, and this whole question of medical legislation is a matter of politics.

THE State of Florida, under the direction of Health Officer Dr. Raymond C. Turck, has established a public radium clinic for the treatment of cancer. In announcing the establishment and aim of this clinic Dr. Turck makes the following statement: "The patient applying for free treatment must be financially unable to pay for any medical services which may be required. Patients who are in moderate circumstances and yet able to make some payment for medical services are *not* eligible for this treatment. It is not the intention of the State Board of Health to enter into competition with private physicians in the treatment of disease." If all public clinics could be established and maintained on that basis there would be an end to this matter of pauperizing the people, and the deserving poor would receive proper medical and surgical services.

THIS year's session of the A. M. A. will be held at St. Louis, May 22-26. It is fortunate that a little earlier date than usual has been selected, for St. Louis is one of the hottest and most uncomfortable places during the time that the A. M. A. ordinarily holds its annual sessions. In May it ought to be fairly comfortable, with none of the hot sticky days that make life unbearable. From all indications there will be an enormous attendance. As usual the programs offer a scientific treat that is attractive, and of course the usual "get-together" and social spirit is a great drawing card. Aside from this there probably will be some interest in the storm that is brewing in medical circles everywhere concerning the tendency toward various forms of socialistic or communistic medicine proposed or innocently supported by some of the leaders of the medical profession.

DR. ALLEN K. KRAUSE, of Johns Hopkins University, recently has called attention to the dangers resulting from promiscuous spitting on the streets and in public places, particularly affecting children who play on the streets, and whose marbles, balls, and other toys are contaminated by sputum. Also, both children and adults have their shoes soiled with such sputum and carry it into the home. It has been said by some of the greatest public health authorities, and by the foremost students of the subject of tuberculosis, that if it were possible to suppress spitting in public places, it would at once effect a very considerable diminution in the prevalence of tuberculosis, pneumonia, diphtheria, whooping-cough and other diseases which are transmitted through respiratory tract discharges. One needs but to glance around on the street or in various public buildings and stairways to note the evidence of promiscuous expectoration and to realize the need of an anti-spitting campaign in Indiana cities and towns.

SENATOR WATSON of Indiana has introduced in the United States Senate a bill to reorganize and to promote the efficiency of the United States Public Health Service. The real object of the bill is not only to provide adequate medical and surgical care for the beneficiaries of the United States Veterans Bureau, and increase the efficiency of the Public Health Service, but also is intended to do away with the temporary commissions in the Public Health Service which are unsatisfactory from every standpoint and are not conducive to efficiency. The Service really needs the addition of 450 medical officers, 50 dental officers, and 50 non-medical but scientific officers, all of whom have been provided for in the bill introduced by Senator Watson. No increase in appropriations is provided, for the reason that no increase will be necessary. The bill simply effects a reorganization of the Public Health Service to meet current needs. As might be expected, the principal opposition to this bill comes from the pseudo-medical cults, and it is hoped that the members of the regular medical profession will get back of the bill in an effort to put it through and thus increase the efficiency of the Public Health Service.

"THE Journal of the Oklahoma State Medical Society, speaking editorially of the training of nurses, holds that a three years' training as a routine requirement is unnecessary.

"There is no good reason why an intelligent woman should be required to give three years of her time in order to master the fundamentals necessary to carry out the orders of the attending physician.

"There is much sentiment of this kind among

members of the medical profession. This sentiment no doubt grows out of the fact of the shortage of nurses who are competent to perform the ordinary duties of caring for patients suffering from general diseases under the direct care of physicians, and on account of the high fees charged which are beyond the reach of a great number of patients. If arrangements could be made which would provide for a one or two years' course of training for intelligent young women and a three years' course for those who desire to prepare themselves for special work, after securing a high school course of preliminary preparation, the public would be much better served than now with a standard three years' course and a large portion of the sick without nurses."—*Journal of the Iowa State Medical Society,* March, 1922.

SOME of our readers may have noticed that some of the life insurance companies, notably the Lincoln Life Insurance Company, makes a practice of sending out questionnaires to all physicians who have attended applicants for insurance, and these questionnaires contain an inquiry concerning the nature of the diseases for which the insurance applicant has been treated, and an opinion as to the effect of such diseases upon the insurance risk. In every instance the giving of this information is classed as a courtesy to the insurance company, but, as usual with insurance companies, no compensation is offered or granted for the time, effort and opinion given, which is purely for the protection of the insurance company. Oftentimes the furnishing of the information requested means looking up old records and furnishing technical advice concerning a patient who has not even paid his bills for professional attention. Even if the bill for professional services has been paid, there the obligation ends, and the attending physician owes nothing more to patient and he certainly owes nothing to the insurance company which, in reality, is the one that profits and is protected by the information furnished. We suggest that the best way to deal with these questionnaires is to throw them in the waste-basket.

From the *Indianapolis Star,* of Thursday, March 23, we clip the following:

HEALTH OFFICER KEEPS SWINE IN TOWN

Fort Branch, Ind., March 22.—Dr. Shaley, health officer here, and four other men were arrested for violating an ordinance passed recently by the town council, prohibiting the keeping of hogs within the corporate limits of the town. When the ordinance was presented many citizens opposed it, including Dr. Shaley.

The health officer and four other accused men appeared in justice's court here today. Their case was tried before a jury, which failed to reach an agreement.

Dr. Shaley, as witness in his own defense, declared that hogs kept within the corporate limits of a town or city are not a menace to health, but are a benefit in that they act as scavengers to keep the streets and premises clean.

If we can place credence in this report, Fort Branch is to be pitied for having a health officer who has such a queer conception of the recognized rules of health and sanitation. Furthermore, it is exceedingly unfortunate that a certain amount of odium attaches to the medical profession because one of its members assumes an attitude so diametrically opposed to all of the teachings of sanitary science which the medical profession upholds. Another phase of the situation is the queer turn of politics which permits or tolerates the appointment of a health officer who is so little in sympathy with the aims and objects of public health work.

"GET WELL IN INDIANA" was the subject of the presidential address delivered by Dr. Eric Crull before the Indiana Tuberculosis Association at its annual meeting on February 24; and "Get Well in Indiana" is a part of the propaganda of the Indiana Tuberculosis Association which it plans to emphasize during the coming year. The mistaken idea that climate alone will effect a cure in tuberculosis induces many people of Indiana and other central and eastern states to uproot themselves from their surroundings and migrate to western and southwestern states without sufficient funds for adequate care and treatment, expecting to obtain light work to maintain themselves. These western and southwestern states are sending out warnings that work of the desired character is not obtainable, that such states have no funds to be used in the care of these individuals, and that untold suffering will result from financial worry and homesickness. It is a proven fact that tuberculosis can be cured right here in Indiana, Illinois, Ohio, etc., just as in Colorado, New Mexico, and California, without the attending financial burden and the necessity of leaving home and friends. Hence the importance of this "Get Well in Indiana" campaign to be put on by the Indiana Tuberculosis Association. A circular dealing with this subject has been gotten out by the Association, and copies will be sent free upon requests addressed to M. A. Auerbach, Executive Secretary, Indiana Pythian Building, Indianapolis.

WE confess that we have been rather disappointed in not having a functionating committee on Industrial and Civic Relations for the Indiana State Medical Association. There are a great many problems confronting the members of the medical profession which ought to be considered by such a committee and recommendations offered for the guidance of the profession.

In this connection we might mention the question of furnishing so much gratuitous but valuable expert information to insurance companies. The profession ought to adopt a definite policy in handling this matter and then stick to it. Another subject of interest is that pertaining to medical and surgical services rendered in industrial cases where the compensation comes from insurance companies. In a large percentage of these industrial cases the doctor is brow-beaten into accepting niggardly compensation, and always because some insurance company is responsible for the claim and will not pay just compensation unless forced to do so. What the medical profession ought to do is to fix its own fees in these compensation cases and not permit insurance companies to do it for them. Furthermore, every doctor should refuse industrial work except under a guarantee by the employers that a just settlement of the account for services rendered will be made. We might mention a number of economic problems that ought to be considered by our committee on Industrial and Civic Relations but what we have mentioned is quite sufficient for a starter.

THE county secretaries are to be congratulated on the successful efforts which they have made already this year in collecting the dues. We now have 2,450 members, which is an increase over the corresponding time last year. It is, of course, the aim of the organization to maintain this lead throughout the year. Reference to the Councilors' membership contest (in another column) will show that the Sixth District, Dr. Spilman councilor, was the first district to increase its membership over last year. This is explained by the fact that out of the eight counties in Dr. Spilman's district, five of them already have 100 percent membership or better. The two lowest in the contest are the Third District, which has only 85 percent of its quota, and the Tenth District, which has 86 percent. The low showing is in a large part due to Washington and Clark counties in the Third District, and to Lake county in the Tenth District. The standing of the county societies shows that Marion County is in first place with 376 members, one less than last year; Vigo County in second place with 105 members, two more than last year; Allen County in third place with 100 members, seven less than last year; Vanderburgh County in fourth place with 91 members, 7 more than last year; and Lake County in fifth place with 79 members, 16 less than last year. At the bottom of the list stand four county societies with six members each at the present time whose memberships for last year were as follows: Whitley County, 19; Johnson County, 16; Washington County, 13; and Warrick County, 12.

A PLAN is on foot in Washington to permit the use of denatured or "premedicated" alcohol in remedies intended for internal administration. In other words, alcohol used in medicine shall be "premedicated" with one or more of the ingredients used in that medicine, and when it is so premedicated, it shall be free from tax. To the average physician, this may sound reasonable and desirable, but when one learns that it is sponsored by the proprietary medicine interests it immediately becomes evident that the matter deserves further scrutiny. Most of the goods of the proprietary medicine manufacturer are sold at fixed prices per bottle. If he can get his alcohol free, that will mean a great reduction in the cost, and a large increase in his profits. On the other side, the pharmaceutical manufacturer who puts out 500 to 2,000 different alcoholic preparations would have to have as many or nearly as many alcohols as he has preparations, instead of three or four formulas of denatured alcohol; he would have to carry an enormous stock of alcohol on his shelves with the attending large capital investment, with no, or at least very little, reduction in cost to the consumer. Further, such a plan would endanger the official standards of preparations, and make the Pharmacopeia a joke. Then, too, the "premedication" would be done in the distilleries, by the distillers' employees, and not by pharmacists and others trained in the handling of pharmaceutical preparations, and thus the scientific control over the manufacture of these drugs would be lost. Summing it up, it seems quite clear that the only one who would benefit by this proposed plan would be the manufacturer of such preparations as Tanlac, Lydia Pinkham's Compound, Etc. The medical profession of Indiana should make it their business to advise the congressmen from this state concerning the dangerous character of the plan.

IF anyone thought that the chiropractors would confine themselves to the manipulations which they call "adjustments", another guess should be made. At the present time the chiropractors are using x-rays, violet rays, radium, high frequency currents, and anything else that will prove attractive to patients and increase fees. This is not all. Not a few of the chiropractors are beginning to use drugs which they dispense themselves and glibly tell the patients are merely to assist in the main treatment, which is "adjustment". In reality it doesn't make very much difference what the chiropractors do or employ, for their sins of omission are as great as their sins of commission when they attempt to treat all kinds of diseased conditions without possessing adequate educational qualifications. However, it is a sad commentary on the judgment of the public when no recognition of fitness is required of those

who are responsible for caring for human lives. We compel a railroad engineer to be thoroughly qualified by education and experience before being permitted to run a locomotive which pulls a train loaded with human lives, and we make sure, through frequent and repeated examinations, that he continues to maintain his efficiency. However, when it comes to assuming the responsibility of a human life that is jeopardized by disease, we throw away all restrictions, forget all the rules of consistency, and permit the ignorant, untrained and inexperienced pretenders to assume the right to care for human life. As we often have said, we care not what system of medicine is employed to treat the disease, providing it has a rational basis, but we do insist that those who are called upon to treat diseases should know the human body in a very general way in health as well as disease, and that knowledge cannot be acquired by the individual who has less than a common school education and attains his title of "doctor" by either a six weeks' or a six months' course in chiropractic training.

CHURCHES are getting down pretty low when they open their doors to medical pretenders for the expounding of unscientific and irrational theories concerning the cause and treatment of disease, to say nothing of giving over the pulpits to an actual clinical demonstration, and yet this is what has occurred in Elkhart where a Methodist church was given over to the chiropractors. According to the newspaper accounts of the meeting, the chiropractic lecturer said to his audience, "We don't accept the theory of disease germs and micro-organisms. We recognize only two diseases—too much or too little functioning. When nerve centers are impinged the functioning ceases. Relieve the pressure and it functions again." Incidentally, it is reported that he said that we should stop paying taxes for the support of regular medical schools.

We are under the impression ourselves that if education does not count for anything in furnishing enlightenment or in adding to the sum total of knowledge, we ought, in justice to the taxpayers, to close all of our educational institutions and especially those educational institutions which have to do with the teaching of all of the cardinal branches of medicine as developed through several hundreds of years of intensive study and investigation. Ignorance is at a premium just now and the public might as well pay the penalty for following blindly in the steps of ignorance. Chiropractic is the deification of ignorance, and those credulous persons who take up with such an irrational and unscientific practice as that followed by the chiropractors not only deserves but will pay the penalty for such foolishness sooner or later. Perhaps it would be best to give the chiropractors full swing in order to demonstrate the absurdity of their claims, but in the meantime a lot of innocent people will suffer as a result of being beguiled by the specious arguments put out. However, it is time for a showdown on this educational proposition and if education counts for anything then make the chiropractors become educated. If education does not mean anything, then by all means it is an injustice to the taxpayers to support educational institutions of any kind.

IN this number of THE JOURNAL will be found some interesting correspondence relating to the attitude of insurance companies toward the medical profession. The insurance companies impose upon members of the medical profession because it can be done so easily and so acceptibly. When we stop to think that the business of life insurance companies is dependent almost wholly upon the skill and judgment of physicians, it seems a little remarkable that due appreciation of this fact should not result in not only decent compensation for services rendered but the display of more courtesy than ordinarily is shown members of the medical profession. Enough evidence can be produced to indicate that the average life insurance company is arrogant and exacting when dealing with doctors, and possesses neither intention nor desire to pay doctors respectable remuneration for the very valuable services rendered. The reason is summed up in the spineless attitude of the medical profession, individually and collectively, in standing up for its rights. By reading the correspondence which we are publishing in this number of THE JOURNAL it will be noted that the burden of responsibility is placed upon the physician. In other words, the insurance company expects the doctor to spend his time and energy, to say nothing of giving his expert opinion, all for the protection of the insurance company but without remuneration or any obligation, implied or otherwise, on the part of the insurance company. Proof of death may be obtained from the public records, as has been pointed out in the correspondence, and if there is any question of doubt on the part of the insurance company as to the proofs thus presented it is up to the insurance company to produce the evidence to the contrary. In reality, what the medical profession should do is to refuse to be the submissive tools of insurance companies, and to that end we suggest that the Indiana State Medical Association take some action on the subject. Expert medical evidence concerning insurance contracts primarily is for the protection of insurance companies, and there is no reason why insurance companies should not pay for such information. However, no

matter for whose benefit the expert services redound, the services should be paid for and not considered a mere courtesy.

THE time has passed for the filing of declarations of those who desire to have their names on the primary election ballots. We doubt if any medical man acting independently or as an officer of the Association has put forth any effort to determine from prospective candidates their attitude concerning medical and public health questions which may come before the next legislature for action. On the other hand, the chiropractors, together with other medical pretenders, have made it a business to secure candidates favorable to their cause, and it is a foregone conclusion that this activity will not cease until such candidates are selected at the primaries and later put into office through election. When the next legislature convenes and a lot of objectionable bills are introduced which threaten to tear down medical education and the laws on our statute books (not enforced) governing requirements for the practice of medicine, a general howl will go up by members of the medical profession as to why the statesmen (?) opposed to medical progress of every form were ever permitted to get into the legislature. It is about time for these howlers to recognize the fact that in this country everything is controlled by politics, and unless we are prepared to get into politics on the ground floor, which means putting up candidates, having them selected at the primaries and after that elected, we are not going to stem the tide of adverse legislation which is proposed and carried into effect by the medical pretenders. The whole attitude of the medical profession is one of "Let George do it". No one seems to want to take the initiative, and whoever is asked to do something feels that he is being imposed upon and promptly shirks responsibility, forgetting that someone must work for the common good. Generally speaking it is the younger men who should be most interested in furthering the aims and objects of the medical profession, and incidentally they are the ones that not only have the most time to devote to the matter but are the most energetic and resourceful. The older and the busier men in the medical profession should give advice as well as financial assistance, but all should contribute to the general cause in some way and until medical men do interest themselves in politics in this way they are not going to accomplish anything beneficial to themselves or the common good. In fact, the prospects are encouraging for the abolition of much of the medical legislation that primarily is protective for the public and only incidentally protects the regular medical profession.

DEATHS

JOHN P. BLACK, M.D., of Greenfield, died March 23, at the age of 69 years. Dr. Black graduated from the Indiana Medical College of Indianapolis in 1885.

EMMA J. FITCH, M.D., died at her home in Indianapolis, February 27, at the age of forty-four years. Dr. Fitch graduated from the Medical College of Indiana, Indianapolis, in 1901.

WILLIAM W. ZIMMERMAN, M.D., of Richmond, died March 20 at the age of sixty-six years. Dr. Zimmerman graduated from the Pulte Medical College at Cincinnati in 1888.

STEPHEN P. TRACY, M.D., of Walkerton, died March 24, at the St. Joseph Hospital in South Bend at the age of sixty-nine years. Dr. Tracy graduated from the Hahnemann Medical College of Chicago in 1886.

CHARLES W. CONGER, M.D., of Indianapolis, died March 16, at the age of fifty years. Dr. Conger graduated from the Medical College of Indiana, Indianapolis, in 1898. He was a member of the Marion County Medical Society, the Indiana State Medical Association and the American Medical Association.

MILO F. HART, M.D., of Kirklin, died March 16 at the Methodist Hospital in Indianapolis, aged forty years. Dr. Hart was a graduate of the University of Indiana School of Medicine in 1909 and was a member of the Clinton County Medical Society, the Indiana State Medical Association, and the American Medical Association.

ELMER EUGENE MORGAN, M.D., of Fort Wayne, died March 23 at the Lutheran Hospital following a brief illness. Dr. Morgan was sixty years of age. He was counselor for the Twelfth District Medical Society, treasurer of the Allen County Medical Society and was a member of the staff of the Lutheran Hospital. Dr. Morgan graduated from the Rush Medical College of Chicago in 1893 and was a member of the Allen County Medical Society, the Indiana State Medical Association and the American Medical Association.

CHARLES MARVEL, M.D., died March 5 at his home in Richmond, aged fifty-eight years. Dr. Marvel was born in Georgetown, Delaware; graduated in medicine from the Jefferson Medical College of Philadelphia in 1891, and located in Richmond in 1894. For more than twenty-five years Dr. Marvel had been on the surgical

staff of the Pennsylvania Railroad Company. He was a member of the Wayne County Medical Society, the Indiana State Medical Association, the American Medical Association, and a fellow of the American College of Surgeons.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in THE JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

CONTRACTS have been let for the erection of a hospital at Clinton.

DR. NORMAN R. BYERS, of Bedford, and Miss Rhoda E. Trook, were married March 15.

THE Grant County Medical Society held its regular monthly meeting at Marion, February 28.

DR. C. F. KERCHEVAL, of Greensburg, has gone to Chicago to take a postgraduate course in surgery.

THE Elkhart Medical Society held its regular meeting at Elkhart, March 2. The meeting was well attended.

THE Wayne County Medical Society held its regular monthly meeting at the Arlington Hotel, Richmond, March 2.

THE annual meeting of the Indiana Hospital Association was held in the Claypool Hotel, Indianapolis, April 19.

THE twenty-third annual meeting of the American Proctologic Society will be held at St. Louis, May 22-23.

DR. SAMUEL G. DOWNING has moved from Tipton to Hobbs, Indiana, where he will take up the practice of medicine.

THE Vigo County Medical Society held its regular meeting at Terre Haute, March 14. Dr. George G. Davis, of Chicago, presented a paper.

DR. HERMAN N. BUNDESON has been made Commissioner of Health of Chicago to succeed Dr. John Dill Robertson, who resigned in February.

WORK has been started on the construction of a tuberculosis hospital at the Marion National Sanatorium. The hospital will cost more than $90,000.

THE LaPorte County Medical Society held a meeting March 10 at Michigan City. A paper on "Focal Infections" was presented by Dr. C. E. Nixon.

THE Huntington County Medical Society held its regular meeting at Huntington, March 7. A paper was presented by Dr. Lucien Smith, of Warren.

THE Wells County Medical Society held a meeting at Bluffton, March 7. Dr. C. L. Blue, of Tocsin, presented a paper on "The Physician of the Future".

THE Jay County Medical Society held a meeting March 9, at Portland. Dr. E. R. Hiatt, of Pennville, presented a paper on "The Laity and Medical Ethics".

DUE to illness, Dr. T. C. Louks, of Terre Haute, has discontinued his practice of medicine in Terre Haute until fall when he hopes to be able to return to his work.

THE Wells County Medical Society held its meeting at Bluffton, February 22. Papers were presented by Drs. E. E. Morgan and W. D. Calvin, both of Fort Wayne.

THE Bartholomew and Jackson County Medical Societies held a joint meeting at Columbus, March 2. Papers were presented by Drs. A. P. Roope and A. M. Kirkpatrick.

DR. FOSTER H. BOWMAN, who has recently returned from New York City, where he took a postgraduate course, has located in Terre Haute for the practice of medicine.

JOHNS HOPKINS UNIVERSITY has received an offer of a gift of three million dollars from an unnamed donor, conditioned on the raising of an additional million by the university.

THE Marion County Medical Society held its regular meeting at Indianapolis, February 28. The principal speaker was Dr. E. C. Rosenow of the Mayo Clinic, Rochester, Minn.

THE regular monthly meeting of the Lawrence County Medical Society was held at Bedford, March 1. Dr. Young, of Louisville, presented the principal address of the meeting.

THE Madison County Medical Society held its meeting at Elwood, March 21. Dr. E. M. Conrad, of Anderson, presented a paper on "Contagious Diseases; Their Cure and Prevention".

SIX million dollars has been given to Johns Hopkins University by the Rockefeller Foundation to be used as an endowment and building fund for the School of Hygiene and Public Health.

THE Daviess County Medical Society held its regular annual meeting at Washington, February 22. Papers were presented by Drs. W. H. Foreman and Walter Pennington, both of Indianapolis.

FOLLOWING the convention of the American Legion in Kansas City, virulent smallpox was reported. It is assumed that a traveler from some distant state brought in an undetected case of the disease.

DR. W. L. MISENER, of Richmond, has returned from Chicago, where he has completed a postgraduate course in surgery. Dr. Misener plans to devote his entire time to the practice of general surgery.

THE Howard County Medical Society held a meeting at Kokomo, March 3. Dr. H. H. Rhorer presented a paper the subject of which was "The Closed Method of Treatment of Infected Abdominal Wounds".

THE University of Cincinnati College of Medicine has received an endowment fund of $224,000 which insures a gift of $7,000,000 from the Rockefeller Foundation and $2,000,000 from the Carnegie Foundation.

DR. C. C. SOURWINE, of Brazil, left March 12th for the East, where he will take up the duties of a major in the regular army. Dr. William Palm, of Harmony, will take care of Dr. Sourwine's practice until his return.

THE Arkansas Medical Society will hold its annual session at Little Rock, May 17-19. This is to be the "homecoming" meeting and it is requested that all doctors formerly of Arkansas, now practicing in other states, make every effort to be present at this meeting.

AFTER twelve years of work in the field of public health work in Tennessee, Dr. Olin West has resigned as Secretary and Executive Officer of the State Board of Health of Tennessee to accept the assignment of Field Secretary of the American Medical Association.

THE anniversary of the birth of Florence Nightingale, May 12, has been set aside as National Hospital Day. National Hospital Day has been made a day on which every hospital may acquaint its local constituency with the workings and aims of the hospital.

THE Rush County Medical Society held its regular meeting March 6, at Rushville. An address was presented by Dr. Leon K. Solomon, head of the medical department of the University of Louisville, Ky., on the subject "New Developments of Treatment by X-Ray".

AT the annual convention in Binghamton, New York state grange favored the plan of Dr. Milton E. Gregg, of Mottville, who proposes that each country community now without a physician erect a home and a small hospital for the use of any physician who will settle there.

A BILL that has been presented to Congress by Representative Hayden forbids either the transportation in interstate commerce or the importation of any peyote or anhalonium or mariahuana or cannabis indica or any of its derivatives. Offenders are punishable by imprisonment or fine.

THE Red Cross Societies of Adams, Blackford, Delaware, Grant, Hancock, Henry, Jay, Madison, Miami, Randolph, Wayne and Wells counties held a meeting in Portland, March 8. Dr. Linn A. Tripp, of Greenfield, presented a paper, the subject being "The County Needs in Red Cross Work".

AT the annual meeting of the Association of American Medical Colleges held in Chicago, March 7, the following officers were elected: President, Dr. Charles P. Emerson, Indianapolis, Indiana; vice-president, Dr. Irving S. Cutter, Omaha, Nebraska; secretary-treasurer, Dr. Fred C. Zapffe, Chicago, Illinois.

DURING March the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: The Intra Products Co.—Sterile Suspension Mercury Salicylate in Cacao Butter; Sterile Suspension Mercury Salicylate in Olive Oil. Meadows Oil & Chemical Corp.—Ammonium Ichthyolate-Meadows.

IT is reported that the board of governors of the London Hospital have announced that no more women students will be accepted, due to difficulty in teaching a mixed class. Women students were first admitted to the London Hospital during the war as an experiment, and the authorities announce that the experiment has been a failure.

THE new clinic building at Fort Wayne, to be known as the Duemling Clinic, was formally opened March 26. The building is a large three-story structure and contains the offices of the following doctors: Herman A. Duemling, Howard L. Norris, Charles G. Beall, Juan Rodriguez, William O. McBride, Victor H. Hilgeman, C. C. Grandy, John T. Short, and Margaret S. Grant.

UNDER the new regulation issued by Internal Revenue Commissioner Blair of the Treasury Department, a year's supply of liquor will be available to wholesale druggists. Under the regulation the druggist may procure an amount of liquor equal to ten percent of the value of his drug business sales during the last year, instead of a supply for only a three-month period, as formerly.

THE appropriations of the children's bureau of the Department of Commerce have been increased by an amendment of the Senate from $80,000 to $120,000 for the purpose of investigating and reporting on matters pertaining to the welfare of children and child life, and particularly to investigate and report on questions of infant mortality and its causes.

THE annual meeting of the American Society for the Control of Cancer was held February 25, at its new office, 370 Seventh Avenue, New York City. The following officers were elected for 1922: President, Dr. Charles A. Powers; vice-presidents, Drs. Clement Cleveland, M. F. Engman, James Ewing and Edward Reynolds; secretary, Thomas M. Debevoise, and treasurer, Mr. Calvert Brewer.

DR. O. C. BREITENBACH of Columbus, Indiana, will sail May 3d on the Empress of Scotland from Quebec, spending three months abroad visiting the leading clinical centers of Great Britain and the Continent. He will be in attendance at the International Congress of Otology to be held in Paris in July. Dr. Breitenbach will be accompanied by his wife and sister-in-law, Miss Louella Folwy of Evanston, Illinois.

THE Hotel Committee for the St. Louis Session of the American Medical Association has announced that at all large hotels at St. Louis there are one or more large rooms with bath which will accommodate from four to six persons. When several persons are coming from the same community these groups can be consigned to one of the larger hotels if they will room together. Parties who desire to use such rooms should write direct to the chairman of the Committee on Hotels, Dr. Louis H. Behrens, 3525 Pine St., St. Louis.

THE dates for the next two examinations of the National Board of Medical Examiners have been announced as follows: Parts I and II, June 19, 20, 21, 22, and 23, 1922; Parts I and II, September 25, 26, 27, 28, and 29, 1922. Applications for the June examination should be in the Secretary's office not later than May 15, and for the September examination not later than June 1. Application blanks and circulars of information may be had by writing to the Secretary, Dr. J. S. Rodman, 1310 Medical Arts Building, Philadelphia, Pa.

IT has been announced in a statement issued by the public health committee of the New York Academy of Medicine that the experiments of prophylactic inoculation against pneumonia carried out during the period of the war and subsequently have not thus far yielded sufficiently convincing proof of its efficacy to warrant universal application. The experiments have established the fact that the vaccines have some value against three of the fixed bacteriologic types of lobar pneumonia and the vaccinations do no harm. The duration of the immunity, however, probably is not more than five or six months.

THE Muncie Academy of Medicine held a meeting March 17 at the Hotel Roberts, Muncie. Dr. H. Kennon Dunham, of Cincinnati, Ohio, presented a paper on "A Few References to Diagnosis, Prognosis and Treatment of Pulmonary Tuberculosis". The paper was discussed by Drs. Alfred Henry, Indianapolis; E. K. Westhaver, Newcastle; and Weir Miley, of Anderson. At the March 31 meeting of the Academy a paper was presented by Dr. James Wynn, of Indianapolis, the subject of which was "Simple Means of Differentiating Types of Tachycardia; and a Reference to Vital Capacity and Its Prognostic Value in Cardiac Disease".

AT the recent annual meeting of the American Society for the Control of Cancer and the Board of Directors, the following officers for the coming year were elected: President, Dr. Charles A. Powers; vice-presidents, Dr. George E. Armstrong, Dr. Clement Cleveland, Dr. Livingston Farrand, Dr. Rudolph Matas; secretary, Thomas M. Debevoise; treasurer, Dr. Calvert Brewster; honorary vice-president, Sir Arthur Newsholme. The following were added to the Board of Directors: Dr. Charles N. Dowd, Dr. John C. A. Gerster, Mr. Calvert Brewster and Mrs. Samuel Adams Clark, all of New York City. The budget for 1922 is $60,000, an increase of $45,000 over last year's budget. Plans were discussed and laid for conducting another "Cancer Week" this year. The membership in the organization at the close of 1921 was 1,821.

THE Committee of Arrangements for the St. Louis Session of the American Medical Association with the cooperation of the St. Louis Convention, Publicity and Tourist Bureau, has made arrangements so that Fellows who so desire can use the Tourist Camp in Forest Park during their stay in St. Louis. This camp accommodates approximately one hundred fifty automobiles. It is equipped with camp stoves, toilet facilities, shower baths, running water and sinks for washing articles of any kind. The camp is located in the western part of Forest Park just off Wells Drive about a quarter of a mile east of Skinker Road. Physicians who wish to camp out during their stay in St. Louis should apply for permits, either directly to Mr. Fred W. Pape, Commissioner of Parks and Recreation, or to the Hotel Committee, Dr. Louis H. Behrens, at 3525 Pine Street, St. Louis.

THE Fort Wayne Medical Laboratory, established in 1905 by Dr. B. W. Rhamy, and one of the pioneer public laboratories in the Middle West, has been incorporated with the following officers and directors: M. F. Porter, Sr., president; A. E. Bulson, Jr., vice-president; M. F. Porter, Jr., secretary; B. W. Rhamy, treasurer and manager; H. O. Bruggeman, L. P. Drayer, D. D. Johnston and I. W. Ditton. The laboratory has greatly enlarged its equipment and the character of its business. Besides being a general diagnostic laboratory equipped for any sort of laboratory examination, it has installed a complete x-ray equipment, including one of the new and powerful twenty-inch x-ray machines for deep therapy, and a complete ultra-violet ray outfit. It also has installed and equipped a laboratory for industrial chemistry for the use of manufacturers, foundries, feed merchants, etc. The laboratory staff includes Dr. B. W. Rhamy, manager and director of the Pathological and Serological Department: Dr. Robert J. Maier, director of X-Ray and Radium Department; and Dr. Paul H. Adams, director of the Industrial and Organic Chemistry Department.

ELEVENTH DISTRICT

At the October (1921) meeting of the Eleventh Indiana Councilor District Medical Association, Dr. G. R. Daniels, of Marion, offered the following resolution which is to be voted upon at the coming meeting to be held May 18, 1922:

"To amend the Constitution and By-Laws of Art. 3. Sec. 2, by adding: and any member who may not attend the meetings of any year may withhold paying the dues for such year without forfeiting his membership."

Art. 3, Sec. 2, that the above resolution proposes to amend now reads as follows:

Sec. 2. (Amended October 16, 1919, to read:) The membership of this association shall consist of members in good standing of the county societies composing this district, who have paid annual dues into this association on or before the opening of the annual meeting on the third Thursday in May of any current year of its existence."

MUNCIE ACADEMY OF MEDICINE

IN MEMORIAM

DR. CHARLES MARVEL

A comrade in our ranks has fallen. A worthy member and co-worker has answered his last call.

Any eulogy, any words of appreciation of our deceased friend and fellow, are as flowers upon a casket, sensed only to the living. Nothing we may do or say will either help or hurt him now. Nor

"Can honor's voice provoke the silent dust,
Or flattery soothe the dull, cold ear of death."

The lesson of every good and noble life is a lesson and a heritage for the living. Therefore, it is altogether fitting that we pause, at this time, to appraise a life so full of devotion and service to humanity; and as an inspiration to us to again close ranks and "carry on". Dr. Marvel was a man of high type, whose personality was as pleasing as it was positive and forceful. He was a fine representative of the cultural standards and scientific training of the physician. Although a busy man he found time for those things which contribute to the moral, intellectual and social betterment. Few of our non resident members were more regular in attendance, and more generously contributed to the success of our meetings.

Therefore, RESOLVED, by the Muncie Academy of Medicine, That in the death of Dr. Marvel we have lost one of our most esteemed members, who stood for the highest and exemplified the best in the profession.

RESOLVED, That we shall hold in grateful memory the warmth of his friendship, the wisdom of his counsel and the loyal support he has given this Academy in its efforts to advance the cause of scientific medicine.

F. G. JACKSON,
W. W. WADSWORTH.
WILL C. MOORE,
Committee.

TIPPECANOE COUNTY

After luncheon on February 28th regular meeting was called to order by President Ruschli. Minutes of previous meeting read and approved without change. Under Report of Committees, the following was submitted:

"The committee as appointed by the President of the Tippecanoe County Medical Society for the consideration of certain irregularities that are at present in existence in our midst, has met and drafted the following resolutions which is presented to the Society for consideration and adoption:

WHEREAS, It is well known that contract lodge, or contract family, practice in any form is contrary

to all ideas of professional ethics; is detrimental to the profession as a whole; and as the ultimate end is conducive of but one condition, namely, inefficient professional service to the patient;

WHEREAS, Recent action of the American Medical Association disapproves of such practice and recommends that local county societies take such action necessary to control and govern such practice;

THEREFORE, BE IT RESOLVED, That the Tippecanoe County Medical Society disapproves of contract lodge or family practice.

COMMITTEE."

Dr. Pyke moved the adoption of the report as read. Seconded by Dr. Romberger. Motion to accept unanimously carried.

Dr. Keiper had the paper of the evening on "Comparative Anatomy of the Eye". Stated his attention first attracted to this subject many years ago when he was asked to examine the eyes of a valuable horse. While he refused to treat horses professionally, still his curiosity caused him to try and examine the eyes, whereupon he soon realized that as compared to the human eye there was a difference in structural anatomy. That soon he began to study the anatomy of all the eyes that his spare time permitted, many of these he sectioned and mounted and after twenty-five years of this work he was prepared to say that he had gained a knowledge through experimentation and study of his own specimens that could not have been acquired by reading the written experience of others.

He gave his processes of preparing specimens and the technique of preparing glycerine jelly for mounting purposes, descriptive of mounting cups used, and how to fill and seal them.

He illustrated his lecture by slides, mountings and books.

The central idea maintained and demonstrated throughout his talk was that the anatomy of the eye of an animal—meaning all life having power of vision—is always suited to its environment. The lantern slides as thrown upon the screen and ably interpreted by the Doctor visualized and illustrated the truth of this statement. The subject matter of the paper bore evidences of years of observations, study and work and opened up new lines of thought, as illustrated by the Doctor when he said in closing, "Will man's flying in the air through the coming years change the anatomical structure of the human eye? This can be answered only by returning one thousand years hence to find out."

Adjourned. Members present, twenty-seven. Visitors, three. WM. M. RESER, Secretary.

Regular meeting called to order March 28th by President Ruschli. In the absence of Secretary, the minutes of the previous meeting were read by Dr. Griest and approved without change.

A communication relative to a bill introduced by Senator Watson protecting those who are in the Public Health Service was read. Dr. Lairy commented upon the status of those who were in this Service merely under contract and as the intent of this proposed bill was to protect them, he moved that we endorse the bill known as Senate Bill No. 2764, and as individuals write to our Senators and Representatives asking them to support the bill. Seconded by Dr. McMahan and carried. Dr. McMahan moved that the President of this Society be empowered to write to our Senators and Representatives indicating this Society's endorsement of the bill. Seconded and carried.

Dr. Hunter announced that at a recent meeting of manufacturers of certain chemicals, as analine dyes and coal tar derivatives, it was requested that a temporary embargo should be placed against the importation of such chemicals until the home industries in these lines get started because Germany is now ready to dump her products on our market at a price way below what our manufacturers could meet. The embargo now existing will soon terminate at which time protection will cease. A bill is in congress for a new three-year embargo which will probably carry our manufacturers to the time when they can meet the foreign competition.

The paper of the evening was by Dr. Paul Risk (dentist), on "Some Aspects of Malocclusion (teeth misplacements), Its Prevention and Correction". It was a very instructive paper illustrated by lantern slides.

Discussion: DR. LAIRY—Hope to soon have laws favoring medical and dental inspection of school children so as to secure early correction of faults.

DR. CROCKETT—Spoke of the pathology of mouths and the things that can be done to improve the conditions.

Comments were made by Drs. Schreiber, Chenowith, Romberger, Hunter, Greist and Ruschli. The latter said it was a large field and very important as a phase of preventive medicine.

Adjourned. Members present, eighteen.

CORRESPONDENCE

DOCTORS IMPOSED UPON BY INSURANCE COMPANIES

Indianapolis, Indiana, March 1, 1922.

To the Editor:

I am much interested and in accord with what you say on page 68, issue of February 15, 1922, concerning imposition by insurance companies upon the profession. In line with this I have adopted a custom which I believe is of value in an attempt to correct some of the evils you have discussed.

We are continually bothered by the different types of insurance companies wanting blanks filled out. Some of the blanks contain forty to fifty questions, others less. It is noteworthy that the companies universally lack the courtesy of filling in the name, address, apparent age, sex, color, occupation, etc. That possibly is due to our past indulgences in doing the extra clerical work for the insurance companies, but it does seem to show how secure the companies are in their belief that they can get much for nothing. They, of course, can and do "pass the buck" and throw the blame on our shoulders whenever possible for their own advantage to avoid fulfilling their contract with the policyholder. As a result of this attitude they do not deserve a great deal of consideration. Again, if we fill out their blanks as they wish, and even occasionally drag out a nominal fee, we are having thrust on us a clerical job that to some at least is an unwanted bother.

My remedy for the situation as it is at present has met with universal surprise, "disappointment in me," and scorn from the companies expecting unwarranted consideration at my hands. When a blank comes to me, I call up the company's office, ask for the manager or his equivalent, and tell him to have his clerk or employed physician (poor goof) call me up and ask for the detailed information bearing directly on the condition of the policyholder in question. The clerk of the doctor can then fill in the blanks, and if necessary mail me the blank to sign, enclosing a self-addressed, stamped envelope. If the company's doctor will not do this, then the company must have a clerk who can take dictation in medical terms on the one or two questions involving technical information or opinion of the physician. If, as has been offered me as an excuse, the company has no clerk trained in taking medical dictation, then they should either get one or cut out the questions necessitating one. Such a system as proposed really argues for quicker completion of the red-tape between the contract and its fulfillment by the company, and ought to prevent blame for failure of fulfillment being passed to the physician.

The agencies here, I have an idea, think that I am acting in a very lordly, high handed way; but as a matter of fact they are getting their desired information more quickly and more sympathetically (which is decidedly to their advantage if they but knew) and are yet getting it for "courtesy". I have been impressed with the attitude of mind which expects me

to do something, or habitually grant favors, for nothing—not even good will or "thank you". On top of this, the ability to feel hurt when I offer a more business-like system would be laughable if the attitude toward me was not such a reflection on the business ability and gullibility of my profession as a whole. Some day perhaps we worms may turn, and wise companies will best take care of their own interests by making it as easy as possible for the physician to give information as he sees best for the policyholder, and also by expressing gratitude as common decency should have told them long ago. Does this meet with your approval, or am I too hard on the benevolent companies?

Sincerely yours,
T. B. NOBLE, JR., M.D.

In connection with the subject of imposition practiced upon doctors by insurance companies Dr. Noble has forwarded for publication some interesting correspondence which is as follows:

Indianapolis, March 17, 1922

Dr. Thos. B. Noble, Jr.,
1008 Hume-Mansur Bldg.,
Indianapolis, Ind.

Dear Sir:

I have been advised that the Claimant in connection with the death of E——— K——— has experienced some difficulty in having you complete your statement of death in order that they may make claim for some insurance that was carried by the deceased, and I am requesting you on behalf of the relatives of the deceased to please complete the attached form, giving the information as it is required on same, and have the form notarized, and then either mail the form to E——— K———, Claimant, or to my office for further action.

Your prompt attention is requested in this matter as the case has been delayed quite a long time pending the receipt of your statement.

Yours truly,
SABADOS, Manager.

—oOo—

Indianapolis, Indiana, March 18, 1922.

Metropolitan Life Ins. Co.,
Indianapolis, Ind.

Dear Mr. Sabados:

Let me take the time and trouble to correct some misstatements in your letter of March 17th. I have had several conferences by telephone with members of your Company on the subject of expediting the completion of your contract with the estate of E——— K———. It seems to me that you or your Company lack the desire to pay the policy as it exists and as you are compelled to by law and moral obligation. Of course it is possible for you to delay payment as long as you please, using one excuse or another, but I refuse to be made the victim of your "buck passing". Let me call your attention to a few facts.

First:—The data "required" by you are entirely unnecessary in every way as a proof of the death of the policyholder. The death certificate in the State House is held on file for your convenience in hastening the settlement of your policy. The data "required" by you are for the benefit solely of your statistical department;—knowing which, and desiring to get the necessary expert opinion for this department, gratis, you claim that without the "proper" answering of your unscientific, voluminous questions, you cannot pay the claim. Understand, you claim this by inuendo, as you appreciate that a direct statement of such would be false. However, the lie is there with the additional attempt to cover your own indifference by directing a manufactured blame onto me.

Second:—You lack all semblance of courtesy and all sense of appearing to appreciate the courtesies granted you in the past in the manner assumed by you in sending your questionnaire. You do not fill in questions numbered 1, 2, 3, 4, 5, 6, 7, and so on, which have nothing to do with any medical aspects of this policy declaration. These should have been filled out by your clerk in order to help me in identifying the policyholder, if for no other reason.

Third:—You expect me to swear to my statement, "required" by you, before a notary—whom I shall pay, I presume. Is this not impertinence on your part?

Fourth:—You say you are requesting me on behalf of the relatives of the deceased to fill out the declaration in question. "What a whopper" that is. Come clean, and substitute "our statistical department" for "the relatives of the deceased".

May I continue by asking you a question or so directly bearing on your Company's attitude toward its policyholders? Why is it, then, that the Metropolitan Life Insurance Company quibbles at the completion of its contracts, or policies, almost universally? Heretofore, we have always filled in your questionnaires without outward objection, but in spite of this our patients report that you require an excessive amount of red-tape before you pay. Do you require the same amount before you accept the payment of premiums? I fancy not.

Let me conclude this unsavory duty by outlining the future. As you are well aware, we are not legally concerned or included by any contract made by your Company. Nor are we to have a moral obligation put upon us at your requisition. As I have said, if you care to do your own work, you can get all of the information you can need by consulting the records in the State House and the family members. If you think it worth while or desirable to retain the good will of the medical profession you will make it pleasantly easy for them to GIVE you the information for your statistical department; and you will kindly, and honorably, accept blame for your own sins of negligence and indifference without attempting to let the family assimilate the impression that the fault lies with their doctor.

Finally, in regard to the claim in question:—as I have previously informed you, I will gladly give your doctor, or clerk, a dictation by phone or otherwise answering the questions which I think pertain to death in question. If you wish my signature, either bring or mail me the policy filled in completely, providing the means of return of the policy, or declaration, or what not. Do we understand each other, henceforth?

THOMAS B. NOBLE, JR., M.D.

—oOo—

Indianapolis, Indiana, March 25, 1922.

To the Editor:

In continuing the series of communications dealing with insurance companies, may I add this note describing the situation here as it exists in regard to the specific claim of E——— K———, deceased, in reference to which I already have written you?

The general manager of the Metropolitan Company here definitely refuses to honor the claim, although he himself is aware of the death of the policyholder and can obtain further proof from the official records. His attitude is that the claim must be based on proper proof of the death, which proof is only supplied by the filling out of the blank by the physician. If I do not fill out the blank, he claims, it will not affect him, as he is not required to pay the claim until I do.

Now it seems to me that the question of what constitutes proper proof of death is not to be arbitrarily settled by the insurance company, even if in the future it should define that definitely in the contracting policy. The agent here seems to worry none at all about consulting the court about this matter, as at all events he could be required to pay no more than the face value of the policy; and, by repeated trips to the courts on different policies, he could of course wear out the pocketbooks of the individuals suing, whereas the company of course has relatively a limitless source of revenue.

I consulted with an eminent lawyer here who has been working for the various companies and is in sympathy with them. His opinion in brief is that: No doctor is required to fill out any blank; the insurance company is not required to pay any claim until he does; the doctor is working for the claimant, not the company in filling out the blanks in question; the proper filling out of the questions is the great prevention of fraud and therefore is a protection for the insurance company; the information secured by the company is of great value to its statistical department; if the company does not consider proof of death absolute without proper filling in of all blanks, a suit will easily establish lawful right to collect on policy, but will be necessary by the attitude of the company. All of which walks us around a circle and leaves us where we started. Although admitting the value to the company of the information secured, Mr. Lawyer does not think that any company is legally obligated to aid the physician in supplying the data. In considering the moral gratitude earned by supplying the data, and moral duty to aid in every way the physician when he supplies data gratis, our lawyer is human and believes that all local offices should be only too willing to meet the physician half way at least.

The crux of this present dilemma is, in my mind, what constitutes absolute proof of death, and is any company to be allowed to remain passively indifferent in securing such proof and yet be entitled to the protection supplied by such proof? Is there any business so important and necessary that it can require unpaid agents, unwilling agents too, to supply its life, protect its very existence, and yet remain indifferent and act hinderingly rather than helpfully? Yet this business pays very high percentages to its agents, not only on initial premiums but upon renewal premiums, so that it is possible for an agent or salesman

to work up a sustaining revenue from renewal subscriptions or premiums and enjoy life without work because you and I keep paying.

Will you kindly suggest some way in which we can get the claimant of the policy of E——— K——— (her mother who was supported solely by the industry of the deceased and who is without income now) paid the face value of the policy? It is a disgrace to leave this poor old lady in want. Believing that I have done more than I am morally obliged to do, and much more than I am legally obliged, I hesitate to give way entirely to the whim of the local Metropolitan agent, as it would only stack up trouble in the future for me. A good, old-fashioned, perforated hickory paddle would be of great service; but these paternalistic times forbid such indulgences. So will you kindly give me a ray of light?

Sincerely yours,
T. B. NOBLE, JR.

THE TRUTH ABOUT MEDICINES

PROPAGANDA FOR REFORM

ANOTHER REMONSTRANCE AGAINST MERCURY INHALATION.—During the last few years the attention of the medical profession has been directed by clever propagandists to the treatment of syphilis by procedures which involve the volatilization of mercury-containing mixtures by heat and the inhalation of the resulting volatile products. There is nothing novel in the principles concerned. Inhalations as well as fumigations of mercury have been tested at various times and the procedures have been abandoned because of the uncertain dosage. The Council on Pharmacy and Chemistry has refused to endorse preparations proposed for the treatment of syphilis which depended essentially on the administration of mercury by inhalation (Spirocide Not Admitted to N. N. R.). In this decision it is sustained by a reinvestigation of the inhalation treatment of syphilis carried out by Cole, Gericke and Sollmann. The investigators point out that the assumption that mercury is more promptly absorbed by the lungs was based on physical misconceptions. In fact, the mercury is condensed on the mucous membranes of the mouth, pharynx and respiratory tract. That in the mouth and pharynx is, for the most part, swallowed; and the absorption then takes place by the gradual conversion of the mercury into soluble compounds. In other words, the administration of mercury compounds by inhalation has no advantage over oral administration. It has the serious disadvantage of indefinite dosage.—(*Jour. A. M. A.*, March 4, 1922, p. 654).

COLLOSOLS (BRITISH COLLOIDS, LTD.).—Collosols is the trade name applied to certain alleged colloidal preparations of drugs made in the Crookes Laboratories by British Colloids, Ltd., London. The Collosols are recommended for external, internal, intramuscular and intravenous administration. A few years ago the Council on Pharmacy and Chemistry investigated the Collosol products and found that some of the specimens contained precipitates and thus they were not colloidal. Commenting on the presence of precipitates, the Council pointed out that if "injected intravenously as directed, death might result, making the physician morally, if not legally, liable". In the cases in which the therapeutic claims for Collosols were examined, the claims were found to be either exceedingly improbable or exaggerated. In the Collosol "literature" there are frequent references to enthusiastic reports by Sir Malcolm Morris, K.C.V.O., F.R.C.S.E. This medical knight seems to have devoted his energies to the exploitation of Collosols and is reported to be one of the directors of the Collosol concern.—(*Jour. A. M. A.*, March 4, 1922, p. 674).

HALE'S EPILEPTIC RELIEF.—According to advertisements in certain cheap weeklies, Hale's Epileptic Relief is "prescribed by the best New York specialists". These advertisements offer to send a $1.50 bottle free. Those who answer the advertisement receive a 4 ounce (118.4 cubic centimeter) bottle of a brown liquid and a small package of tablets, also a sample box of Hale's Liver Tablets. The American Medical Association Chemical Laboratory analyzed these preparations, and reported that the preparations give tests for ammonium, sodium, potassium and bromids, and that the bromid content is equivalent to 20.73 gm. of potassium bromid per hundred c.c. The tablets were found to contain emodin bearing (laxative) drugs—possibly aloes.—(*Jour. A. M. A.*, March 4, 1922, p. 672).

MORE MISBRANDED NOSTRUMS.—The following preparations have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Krause's Phosphorets (Norman Lichty Mfg. Co.), consisting essentially of ferrous carbonate, asafetida and traces of phosphorus and claimed to cure diseases resulting from a shattered nervous system. Binz Bronchi-Lyptus (Edward G. Binz), consisting essentially of a solution containing oils of eucalyptus and peppermint, glycerin, sugar, acacia, alcohol and water, and claimed to be an efficient remedy for croup, whooping cough, sore throat, etc. Dr. Goodwin's Herbal Compound (Dr. F. A. Goodwin), a mixture of plant material containing chiefly senna, fennel, uva-ursi and unidentified plant extractives, and sold for diseases of the stomach, liver, kidneys, nerves, bowels, bladder, etc. Dubois Pecific Pills (W. J. Baumgartner), consisting essentially of aloes, ferrous sulphate, calcium carbonate and sugar, claimed to be a reliable female tonic, etc. 4-11-44 Capsules and Injection (A. J. Benson), the capsules containing cubebs and copaiba, and the liquid, a solution of zinc sulphate and salt, sold for the treatment of gonorrhea, etc. Metzger's Catarrh Remedy and Speis Oil (Metzger Mfg. Co.), the first consisting essentially of iodid and mercuric compound, gentian, alcohol and water, and the second consisting essentially of gasoline, oil of eucalyptus, methyl salicylate, menthol, camphor and ether.—(*Jour. A. M. A.*, March 4, 1922, p. 672).

MORE MISBRANDED NOSTRUMS.—The following preparations have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Blummer's Herb Tea (Lincoln Chemical Works), a mixture of althea, licorice, couchgrass, sage, senna, elder flowers, sassafras, anise, fennel, melissa, American saffron, German chamomile, dandelion, liverwort and lungwort, sold as a blood purifier, etc. Parry's Vegetable Compound (Parry Medicine Company), consisting of alcohol, olive oil, water and flavoring, and recommended for various diseases. Hall's Catarrh Medicine (F. J. Cheney & Co.), consisting essentially of potassium iodid, plant extractives, cardamon, sugar, alcohol and water. LaDerma Vagiseptic Discs (Palestine Drug Co.), consisting essentially of common salts, a small amount of alum, sugar, starch and talc. Women's Pills (Fitzpatrick Drug Co.), consisting essentially of castile soap, alkaline carbonates, and unidentified plant extractives.—(*Jour. A. M. A.*, March 11, 1922, p. 751).

OUR KNOWLEDGE OF VITAMINS.—It is generally accepted that a well-balanced diet provides the individual with such vitamins as are necessary to maintain growth and nutrition. The *British Medical Journal* in a leading editorial reiterates the statement that an abundant supply of vitamins exists in all fresh vegetables and that a considerable quantity occurs in milk and meat, provided the latter substances are obtained from animals fed on fresh foods. A normal adult living on an ordinary diet containing

a reasonable proportion of fresh vegetables is, therefore, certain of obtaining a plentiful supply of vitamins. Of all the mass of evidence which has accumulated relative to these substances, this fact is the point of greatest importance. It is, however, very unfortunately, the one point which those commercially inclined are unwilling to recognize.—(*Jour. A. M. A.*, March 11, 1922, p. 734).

PULVANE.—In a twelve-page pamphlet, sent out by the Pulvane Laboratories, Inc., Des Moines, Iowa, and purporting to deal with "The Therapy of Pulvane, an Advanced Method for the Treatment of Respiratory Diseases," we are told that Pulvane "was developed in a United States Army General Hospital by officers of the Medical Department". Pulvane is administered by inhalation, at the offices of the Pulvane Laboratories, Inc. Its "discoverer", it is declared, chanced on the method of "introducing into solution and volatilizing a certain germicide, extremely rare in its usage, because of its resistance, heretofore, to attempts to bend it to scientific will". This "rare" medicament is alpha naphthol. But since the discovery of this volatilizing method "three other ingredients of high therapeutic value have been added". It is stated that the "medical directors" will be glad to name every ingredient of Pulvane to any reputable member of the profession. Nothing is said about disclosing the amounts of the ingredients of Pulvane and hence the information offered is no more complete than that furnished for such patent medicines as Peruna. With regard to the claim that Pulvane was "developed in a United States Army General Hospital by officers of the Medical Department," Surgeon-General Ireland of the United States Army announces that the Medical Department of the Army had nothing whatever to do with the matter and that it thoroughly disapproves of the methods of the promoters of the concern.—(*Jour. A. M. A.*, March 11, 1922, p. 750).

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act: Devonia Mineral Water (Devonian Mineral Springs Co.), claimed to be a natural tonic and reconstructor, and to be indicated in chronic indigestion, constipation, rheumatism, etc. Jackson's Home Rheumatism Remedy (Mark H. Jackson), composed of aloes, licorice, cornstarch and Blaud's mass, and claimed to be a treatment, remedy and cure for gout, rheumatism, lumbago, sciatica and scrofula.—(*Jour. A. M. A.*, March 18, 1922, p. 834).

WARN'S EPILEPSY TREATMENT.—The claims made for this nostrum are similar to those made for Maghee's Epilepsy Treatment, but they are worded more cautiously. While in the case of the Maghee preparation it is claimed that certain effects *will* be produced, the Warn Remedy Co. avers that these effects *should* be produced by the preparation. The A. M. A. Chemical Laboratory reports that Warn's Epilepsy Treatment consists of capsules, each containing approximately 0.06 gm. (1 grain) of phenobarbital (luminal) to which has been added some charcoal and that it differs but slightly (by absence of bismuth subnitrate) from Maghee's Epilepsy Treatment analyzed previously.—(*Jour. A. M. A.*, March 18, 1922, p. 834).

THE FUTURE INDEPENDENCE AND PROGRESS OF AMERICAN MEDICINE IN THE AGE OF CHEMISTRY.—The recent war brought about a realization of how dependent we had been on Germany for our most valuable drugs. However, before the war was over, American manufacturers were making adequate supplies of urgently needed drugs. In their work on war gases chemists had an example of what could be accomplished in an almost incredibly short time, when facilities for research were provided on a large scale and under conditions allowing of the fullest cooperation of chemists, physicists and physicians. With the close of the war, chemists began to consider to what extent such facilities might bring about American independence in drugs. A committee appointed by the American Chemical Society has now issued a report which elucidates the subject. The report makes it clear that pharmacologic research in German universities and in privately endowed institutes are far ahead of those in the United States. Our schools of medicine and hygiene, the report continues, are largely ignoring the services which pharmacology, in close cooperation with chemists and clinicians, can render to hygiene and preventive medicine. About twenty years ago, Congress established the Hygienic Laboratory of the U. S. Public Health Service; the plan of its organization was unsurpassed by that of any laboratory in the world; but since then Congress has failed to provide for any considerable growth of this laboratory. Enlarged and with adequate support, this laboratory could give the United States the leading place in the world in this great scientific and humanitarian endeavor toward the discovery of new drugs. If better government support of the Hygienic Laboratory cannot be secured, then a privately endowed research institute must be the goal of those who realize the vast benefits which will accrue from the proper type of research in drug therapy.—(*Jour. A. M. A.*, March 18, 1922, p. 806).

THE DEMAND FOR VITAMINS.—Ordinary fresh foods are the simplest, cheapest and richest sources of vitamins, yet vitamin "concentrates" are being "demanded" by the public because shrewd, forward-looking "patent medicine" exploiters are using all the subtle art of modern advertising to convince the public that it is in serious danger of vitamin starvation, and that the only hope lies in buying these alleged concentrates to make up a hypothetic deficiency. Advertising campaigns, such as these of the vitamins constitute a vicious circle; an artificial demand is created and then the manufacturer excuses his business on the ground that he is merely supplying a demand.—(*Jour. A. M. A.*, March 18, 1922, p. 810).

VERATRUM VIRIDE IN PNEUMONIA.—Medical opinion is averse to the routine use of veratrum viride in the treatment of uncomplicated pneumonia. Claims made for the use of veratrum viride are advanced for other drugs, none of which has borne critical investigation. The error on the part of those who make these claims is the result of inadequate control observations. Advocates of veratrum viride, aconite and venesection believe that by the depression of the circulation produced by the treatment, they may lessen the extravasation of blood into the air vesicles and to this degree lessen the involvement of the lungs. The lack of demonstrable success of venesection has led to the discarding of this once almost universally employed mode of treatment of pneumonia. It is unreasonable to expect as much or more from aconite or veratrum than from venesection.—(*Jour. A. M. A.*, March 18, 1922, p. 835).

ALBERT ABRAMS, A.M., M.D., L.L.D., F.R.M.S.—Dr. Abrams has published a book on "Spondylotherapy" ("Physio-Therapy of the Spine"). Spondylotherapy is stated to concern itself "*only* with the excitation of the functional centers of the spinal cord". Between 1912 and 1914 Dr. Abrams gave "clinical courses" on "Spondylotherapy" in various parts of this country. More recently Dr. Abrams had advertised that he gives a "course" in "Spondylotherapy" in San Francisco. In addition to "Spondylotherapy", Dr. Abrams has also evolved what he calls the "Electronic Reactions of Abrams" which

are said to make possible long-distance diagnosis, it being necessary only to send a few drops of blood taken from the patient and allowed to dry on a slide. Dr. Abrams founded and edits "Physico-Clinical Medicine", a quarterly "devoted to the study of the Electronic Reactions of Abrams". What seems to be the outstanding piece of apparatus, devised or invented by Dr. Abrams, of physico-clinical diagnosis and treatment is the "Oscilloclast". All one needs to do, according to Dr. Abrams, is to ascertain the "vibration rate of a drug" and then to substitute the same vibration as produced by the "Oscilloclast". More recently, Dr. Abrams has extended his observations and experiments, using what apparently is a modification of the old-fashioned pith ball suspended by a silk thread from a rubber rod. This device he calls the "Electrobioscope". If there is any scientific foundation for the marvels that Dr. Abrams so picturesquely features, the scientific world has not yet found it out.—(*Jour. A. M. A.*, March 25, 1922, p. 913).

BOOK REVIEWS

THE OPHTHALMIC NURSE. By G. Griffin Lewis, M.D., F.A.C.S. 102 illustrations. Cloth, 176 pages. W. B. Saunders Company, Philadelphia and London.

This little book answers the needs of the ophthalmic nurse and is written to serve as a practical guide for nurses who lack special training in the management of ophthalmic cases. It is written in a very plain, understandable way, and well illustrated. It gives correct ideas regarding the anatomy, physiology and hygiene of the eye, and includes a knowledge that will give sufficient proficiency to enable any intelligent nurse to meet any requirement of the ordinary ophthalmic case.

LESSONS ON TUBERCULOSIS AND CONSUMPTION, by Charles E. Atkinson, M.D. Illustrated. Cloth, 470 pages. Price, $2.50. Funk & Wagnalls Company, New York and London.

As the title indicates, this is a book for the household showing how to prevent tuberculosis, how to recognize its first symptoms and how to win back health if possible to do so. There are chapters on how the disease is spread, how recognized and how nature heals. There are also chapters pertaining to rest and exercises, the abuse of fresh air and climate, what to eat, and good sound advice concerning treatment and surgical measures. The chapters on climate are especially illuminating as indicating the character of climate to be selected for individual cases. In short the book covers in a comprehensive way the questions concerning every tuberculous patient and is written for popular reading and study.

THE BLIND; Their Condition and the Work Being Done for Them in the United States. By Harry Best, Ph.D. 765 pages. Cloth, $4.00. The Macmillan Company, New York.

This is a very interesting presentation of the condition of the blind in the United States and what is being done for their welfare. The various chapters take up the discussion of the legal treatment of the blind, their economic condition and cost to the State, as also a discussion of the subject of the prevention of blindness and the relation of blindness to heredity, disease and accidents, as also an extended discussion of the subject of education of blind children with special reference to the use of raised print and libraries for the blind. Special chapters have been devoted to the consideration of industrial establishments for the blind, including the employment of the blind in general occupations. The book concludes with chapters on organizations interested in the blind, and the provisions by the national government for caring for those who were blinded in war. To those who are interested in the problem of how best to care for the blind the book is especially interesting and instructive.

ULTRA VIOLET RAYS IN MODERN DERMATOLOGY. By Ralph Bernstein, M.D., Professor of Dermatology, Hahnemann Medical College, Philadelphia, etc. Illustrated. 162 pages. Cloth. Achey & Gorrecht, Lancaster, Pennsylvania.

In reality, this book reports the results of the clinical experiences of the author with the use of ultra violet radiations in the treatment of the various skin diseases. While the efficacy of ultra violet rays in the practice of dermatology is now thoroughly established, yet the author admits that in some cases the treatment is not as successful as one might desire, and he has no hesitation in drawing deductions therefrom. He is not over-enthusiastic, but gives credit to the ultra violet rays for some rather startling results in those cases where bacteriacidal action and antipruritic and analgesic effects, as well as its reconstructive effect upon epidermal cells, is desired. No particular attention is given to the bacteriology and pathology of dermatological diseases, and the case histories do not go into detail but summarize the experience in treatment with the ultra violet rays. While many of us may not be inclined to give as much credit to ultra violet rays, yet the recommendations borne out by the case reports open up an interesting field of study and therapeutic use of a relatively new agent.

SUBMUCOUS RESECTION OF THE NASAL SEPTUM, by William Meddaugh Dunning, M.D., Surgeon, Bronx Eye and Ear Infirmary, New York, etc. Cloth, one hundred pages. $1.50. Surgery Publishing Company, New York City.

This little book describes the commoner septal deviations and the author's method of correcting the same by submucous resection. The description is comprehensive and is well illustrated. As the author well says, the operation is one of the most important ones in the field of surgery in that it requires great care and skill in its performance, the adoption of methods to avoid serious results, but the end result when the work is performed according to the best technique gives as much satisfaction to the patient as any procedure in the field of operative surgery. Many skillful operators vary to some extent from the plan followed by the author, but no one can go astray by following the suggestions that have been given.

RADIANT ENERGY AND THE OPHTHALMIC LENS, by Frederick Booth. Cloth, 225 pages, 230 illustrations. Price $2.25. P. Blakiston's Son & Co., Philadelphia.

This little book is a study of the principles of optics and furnishes a grounding in the fundamentals of refraction. The chapters include a brief discussion of the anatomy of the eye, a discussion of the various theories concerning light, including the various rays and color, the mechanics of vision, theories and treatment of refraction of the eye, including

The Endocrines, Digestive Ferments, Catgut Ligatures, etc.

THE ARMOUR LABORATORY is maintained for the purpose of handling the glands, membranes and other raw materials supplied by our abattoirs in immense quantities, from which important therapeutic agents are extracted and fabricated.

Among the products that the physicians and surgeons use daily are:

Corpus Luteum; Suprarenals, U. S. P.; Parathyroids; Pituitary, Whole Gland; Pituitary, Anterior; Pituitary, Posterior; and other glandular substances in po. and tabs. Pituitary Liquid in 1 c. c. and ½ c. c. ampoules.

Armour's LABORATORY PRODUCTS

Suprarenalin Solution 1:1000; Suprarenalin Ointment 1:1000; Pepsin, U. S. P.; Pancreatin, U. S. P.; and other preparations of the Digestive Ferments that are used in stomachic and intestinal disorders and as vehicles for nauseating drugs.

We also make Sterile Surgical Catgut Ligatures, plain and chromic, boilable; and Iodized Ligatures, nonboilable. ¶The Armour ligatures are made from Lambs' gut; selected especially for surgical purposes and sterilized at opportune stages in such manner as to preclude the possibility of contamination in the finished strings.

We are headquarters for the Organotherapeutic Agents and are always glad to co-operate with the medical profession

SAVE MONEY ON YOUR X-RAY SUPPLIES

Get Our Price List and Discounts on Quantities Before You Purchase

HUNDREDS OF DOCTORS FIND WE SAVE THEM FROM 10% TO 25% ON X-RAY LABORATORY COSTS

AMONG THE MANY ARTICLES SOLD ARE

X-RAY PLATES. Three brands in stock for quick shipment. PARAGON Brand. for finest work; UNIVERSEAL Brand, where price is important.

X-RAY FILMS. Duplitized or Double Coated—all standard sizes. X-Ograph (metal backed) dental films at new, low prices Eastman films, fast or slow emulsion.

BARIUM SULPHATE. For stomach work. Finest grade. Low price.

COOLIDGE X-RAY TUBES. 5 Styles. 10 or 30 milliamp.—Radiator (small bulb), or broad, medium or fine focus, large bulb. Lead Glass Shields for Radiator type.

DEVELOPING TANKS. 4 or 6 compartments stone, will end your dark room troubles. 5 sizes of Enameled Steel Tanks.

DENTAL FILM MOUNTS. Black or gray cardboard with celluloid window or all celluloid type, one to eleven film openings. Special list and samples on request. Price includes your name and address.

DEVELOPER CHEMICALS. Metal, Hydroquinone, Hypo, etc.

INTENSIFYING SCREENS. Patterson, TE, or celluloid-backed screens. Reduce exposure to one-fourth or less. Double screens for film. All-metal Cassettes.

LEADED GLOVES AND APRONS. (New type glove, lower priced.)

FILING ENVELOPES with printed X-Ray form. (For used plates.) Order direct or through your dealer.

(Continued from page 146)

accommodation and conversions, and winds up with chapters concerning the practical application of lenses for correcting vision. These latter chapters cover the use of cycloplegics, methods of testing the vision with lenses, the use of retinoscopy, ophthalmoscopy, fitting of frames and mountings, and rules for transposition of lenses.

THE NEW POCKET MEDICAL FORMULARY, by William Edward Fitch, M.D., formerly lecturer on Surgery, Fordham University, School of Medicine; attending physician to the Vanderbilt Clinic, etc. Thirtieth edition, revised. Cloth, $2.50. F. A. Davis & Co., Philadelphia, 1921.

This little pocket medical formulary has been compiled from the results obtained from medical men of wide research and ripe experience. It really represents the pet formulæ of not only the author but many medical men of wide experience. The new edition really introduces prescriptions containing the more important recently discovered drugs that have been found useful. The subject matter has been conveniently arranged, the diseases being in alphabetical order so that prescriptions pertaining to any of them may be found readily. There are other additional features like diet lists, table of differential diagnosis, hospital tables, etc., to add to the value of the book.

DISEASES OF THE SKIN, by Richard L. Sutton, M.D., Professor of Diseases of the Skin, University of Kansas School of Medicine, etc. 1132 pages, 969 illustrations with 11 colored plates. Fourth edition, revised and enlarged. Cloth, $9.50. C. V. Mosby Company, St. Louis.

Like many other fields in medicine, dermatology has made rapid advances during the last few years, and while the author's previous editions of his work on diseases of the skin were considered comprehensive and up to date, yet this last or fourth edition marks a distinct advance by adding all of the late advances. This includes revision of many chapters and the addition of considerable new material. The book also has been made more useful by the addition of a number of new illustrations. Perhaps no treatise on skin diseases devotes more attention to pathology. As in former editions of the work the stress placed upon symptomatology, diagnosis and treatment in the final analysis is what interests the general practitioner. This has been done in a clear and concise manner consistent with comprehensiveness. This latest edition should meet with the same approval that has been given former editions. It is the product of not only a teacher but an experienced clinician, and while he gives his own conclusions he does not hesitate to incorporate the conclusions of others.

OPTIMISTIC MEDICINE, by A Former Insurance Man. Cloth. 320 pages. $3.00. F. A. Davis & Company, Philadelphia.

This is a very entertaining book which may be read with profit by every general physician. In reality it is a plea for optimism as a remedial measure in the physician's contact with his patients. It is well known that a cheerful, optimistic physician often works mental miracles with his patients, and he sometimes acquires a greater reputation for skill in the use of drugs than he deserves, inasmuch as the credit belongs to the optimistic atmosphere created by the doctor. It is apparent that in every family the utmost of courage, hope and optimism should be brought to bear on the patient to direct his mental attitude in the right direction. The pessimistic doctor should change his business. The optimistic physician cannot rely upon optimism even though that counts for much in the successful handling of his cases, for he must of necessity adopt those medical and surgical measures which the nature of the case demands. In other words, his optimism must be coupled with integrity and professional attainments. He should never resort to the stock in trade of the quack. The author discusses the whole subject from the viewpoint of doctor and patient, from youth to old age, and, in connection with various conditions which call forth the physician's services. Incidents humorous and otherwise enliven the text, and much food for thought will be found in the endeavor to point out the necessity of maintaining an optimistic attitude at all times if a man or woman would preserve a sound mind and a sound body.

DISEASES OF THE SKIN, by Oliver S. Ormsby, M.D., Professor and Head of the Department of Skin and Venereal Diseases, Rush Medical College, etc. Second edition. Octavo of about 1166 pages, illustrated. Philadelphia and New York: Lea & Febiger. Cloth, $10.00 net.

This is a reconstruction of the former edition and for the distinct purpose of incorporating new material. This new material includes a description of fifteen new diseases and the rewriting of practically all of the balance of the book in order to bring it up to date. A reason for the appreciation that has been accorded this book is that the author has not tried to make it an explanation of his own opinions only, but he has reviewed the dermatological literature with a view of incorporating within the book the recognized opinions of others. These references will serve as a guide to the student who is working up any particular subject. The classification of the previous edition has been followed. The introduction deals mostly with anatomy and physiology of the skin, together with a general consideration of etiology, pathology, diagnosis, prognosis and therapeutics. This is followed by a classification of diseases, which includes hyperemias and inflammations, hemorrhages, hypertrophies, atrophies, pigment anomalies, new growths and neuroses. There are also chapters on parasitic affections, under which is discussed diseases due to both vegetable and animal parasites. The chapters on diseases of the appendages include diseases of sweat glands, sebaceous glands, nails, mucous membranes, the hair and hair follicles. The author emphasizes the importance of a good working knowledge of the microscopic anatomy and of the physiology of the skin. In the chapter on diagnosis a special reference is made to the Wassermann test for syphilis, Noguchi Luetin test for syphilis, tuberculin, Von Pirquet and other tests for tuberculosis, in addition to much other information of value in the general and special examination of the patient. In the consideration of therapy much advanced information concerning radiotherapy, which includes x-rays and radium, phototherapy, vaccine therapy and the technique for treatment with liquid air and solidified carbon dioxide is presented. The author is a well-known clinician and teacher, and the first edition of his book gained deserved popularity, so that this second edition should receive hearty welcome.

CALCREOSE

CALCIUM IN INTESTINAL TUBERCULOSIS

"The administration of calcium chlorid in tuberculous diarrhea is, we believe, based on empiricism, but of its good effects there are at present many undeniable examples. . . . We have used calcium chlorid in no sense as a curative agent, but merely as a palliative in an attempt to control the distressing symptoms of pain and diarrhea."—P. H. Ringer and C. I. Minor, Am. Rev. Tubere. 5:876 (Jan.) 1922.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal parts of creosote and lime.

CALCREOSE has the same actions and uses as creosote but is free from its untoward effects on the stomach. Creosote is used as an intestinal antiseptic.

STREPTOCOCCIC OSTEOMYELITIS OF THE TEMPORAL BONE

HARRY BOYD-SNEE, M.D.

SOUTH BEND, INDIANA

What I am about to observe I have recorded in a group of cases numbering in all 266 individuals. The disease being bilateral in 29 made it possible to explore the region in 295 instances. The diagnosis in every case was established by findings in operation and cultures taken from the diseased areas. Further supplementary corroborative autopsy findings were available in 22 cases.

In every case but one, attention was first attracted to the region by the development of an acute otitis media or an acute exacerbation of a chronic otitis media. The otites supervened in the course of the following acute infectious diseases: Measles, 87; acute naso-pharyngeal infection, 108; acute streptococcic bronchitis, 12; scarletina, 20; streptococcic pneumonia, 15; influenza, 20; epidemic parotitis, 2.

In 136 patients, 24 of whom presented bilateral involvement, we had the opportunity to check the bone findings against the preoperative middle ear findings in 160 instances. In every instance the streptococcus was recovered from the tympanic exudate before the operation and the same organism was again recovered either in pure culture or mixed with other pyogenic organisms from the infected cancellous bone through the operative wound. Supported by these findings I feel justified in making this statement:—that recovery of the streptococcus from the tympanic exudate in the presence of an acute inflammatory reaction in the middle ear is pathognomonic of acute osteomyelitis in the bone beyond the boundaries of the middle ear tract, comprehending the medullary and pneumatic spaces in the petrous and squamous portions as well as the mastoid process of the temporal bone. If this conclusion can be accepted, and it has been established in 100 percent corroborative middle ear and bone findings in this particular group, then the diagnosis will carry with it everything in the way of complications as they exhibited in the cases. Further let me say that recovery of the streptococcus from the tympanic exudate at once excludes the diagnosis of acute otitis media, *per se*, with its limitations, and also the diagnosis of acute mastoiditis for the same reason, since neither diagnosis comprehends the localities in which the disease has been found to exist. On the other hand the diagnosis of acute streptococcic osteomyelitis of the temporal bone covers the exact pathology found and signifies a regional infection without limitations, and let me add that it is an anticipating diagnosis carrying with it a guarded prognosis for it anticipates any of the complications whether regional or general which exhibited clinically in this group of cases.

The infected region in every case was reached through an operative wound and the pathology uncovered varied with the case and in bilateral operations were not identical. The variations in type will be best understood if I consider the subject in regular sequence as the different elements of the bone suffered through invasion by the streptococcus. Invasion occurred by contiguity or was hemotogenous. The immediate effect on the tissues invaded was characterized by the development of an inflammatory reaction involving primarily the vascular structures of the bone. The bone marrow in the medullary spaces and the mucosal lining of the pneumatic cells were the first tissues to suffer in the reaction and the condition was identified by characteristic vascular infiltration of the pneumatic and medullary spaces with granulations bathed in a sero-mucosanguinous exudate. The periosteum participated in the initial reaction in but a few instances, it was distinguished as primary in several of the cases in which otitis media developed as a complication in the course of a scarletina. The dura became primarily involved in two cases, evidence of such involvement being uncovered by autopsy. In this discussion I shall consider periostitis and external pachymeningitis as secondary complications rather than primary manifestations of invasion of the temporal bone by streptococci.

The causal agents in this initial process ap-

pear to have been the streptococcus, as this organism was recovered in pure culture from the infected medullary spaces in every case where the diseased region was reached before suppuration supervened and during the period in which the inflammatory reaction was limited to the vascular structures. The infective microorganism reached the region in two ways, namely, by direct extension from the adjacent infected tympanic cavity or middle ear tract, or through the infected blood stream.

These are the pathological and bacteriological findings in the cases I have diagnosed acute, uncomplicated streptococcic osteomyelitis of the temporal bone.

Sooner or later the bone itself became involved secondarily, osteitis supervening, as was evidenced by disintegration of the trabeculæ and erosion of the denser compact bone. With the development of osteitis the meninges and the periosteum became secondarily involved *per extensionem*. In the event of intracranial extension the neighboring parts in the adjacent region suffered in proportion to the extent and character of the tissues invaded and the following complications developed: External pachymeningitis, perisinusitis, thrombo-sinusitis, leptomeningitis, encephalitis, bulbo-myelitis and encephalo-myelitis. Direct intracranial extension occurred clinically in 30 individuals, involvement manifesting itself as follows: Perisinusitis, 17; thrombo-phlebitis of the sigmoid sinus, 5; thrombo-phlebitis of the superior petrosal sinus, 1; temporo-sphenoidal abscess, 5; cerebellar abscess, 1; extradural abscess in middle fossa, 4; and streptococcic leptomeningitis, 21. Streptococcus was recovered in every instance. On the other hand when extension developed extracranially the complications varied according to the locality and the tissues invaded and are recorded as periostitis, dermatitis infectiosa, myositis, thrombo-phlebitis and lymphadenitis; exhibiting clinically as parietal abscess 1, subtemporal abscess 2, cervical abscess 3, facial paralysis 4, and erysipelas 14. The labyrinth had escaped in every instance.

The foregoing comprehends the regional complications which developed through direct extension of the inflammatory process from the primary focus of infection in the temporal bone.

Through the blood stream remote organs and tissues suffered from metastases and from endotoxicosis and bacteremia, manifesting as metastatic abscesses, arthritis, optic neuritis, nephritis, pleuritis, endocarditis, myocarditis, cellulitis and general diffuse erythematous dermatitis. These complications are proof that bacterial toxins and bacteria as well as infected emboli from the primary focus gained access to the lymph and blood vessels and entered the general circulation.

The causal agents were found to be the streptococcus in mixed strains or the streptococcus mixed with other pyogenic cocci (staphylococci and pneumococci) or bacilli (pyocyaneus, influenza and diphtheroids).

What has been said sets forth the pathological and bacteriological findings in the cases of this group which I designate acute, complicated, suppurative streptococcic osteomyelitis of the temporal bone.

The clinical picture of acute, uncomplicated streptococcic osteomyelitis of the temporal bone may be said to be that of acute, suppurative otitis media and there is no variation. The symptomatology in acute, complicated streptococcic osteomyelitis of the temporal bone is variable and will coincide with whatever complication, single or multiple, which supervenes. In these cases of mixed infection, general and local symptoms appear in regular order as extension progresses. The time when we may expect to observe external localized evidence of disease like sagging of the postero-superior meatal wall or to elicit tenderness on pressure over the mastoid or antral regions is only after osteitis has supervened and the periosteum has become secondarily involved; likewise symptoms indicative of meningeal irritation appear when the inner plate suffers erosion with coincident dural involvement.

The classical symptomatology of acute, suppurative mastoiditis is no guide in the diagnosis of this atypical phenomenon; there need be no sagging, no tenderness on pressure, no elevation of temperature, no change in the structures over the mastoid, leucocytosis is a variable incident, and yet whenever the streptococcus has been demonstrated in the course of an acute, suppurative otitis media even if subsequently other organisms have submerged that bacterium and even if complete resolution as far as the middle ear is concerned has been established, nevertheless a focal infection still exists beyond this area in the bone marrow or in the mucosal lining of the pneumatic cells in the temporal bone.

The findings in roentgenograms were variable, they were reliable and corroborative only in the cases of the suppurative type of the disease but were not so valuable in a diagnostic way if the plates were taken before the period characterized by suppuration and coincident bone destruction.

Mortality:—In 24 the termination was fatal and in 22 autopsy was done. The causes of death were found to be: Pneumonia, 2; metastatic septicopyemia, 1; streptococcic leptomeningitis, 21; the latter complicated with cerebral abscess, 5; with cerebellar abscess, 1; with sigmoid sinus thrombosis, 5; with superior petrosal sinus thrombosis, 1.

Great importance attaches to the method by

which specimens are recovered from the middle ear and I wish to say that the customary practice of recovering the specimen on a sterile cotton tipped swab which has been dipped into the external auditory canal when it is filled or partially filled with blood, serous exudate or pus proved to be faulty technic; many of the swabs innoculated in this manner were reported contaminated or negative and had to be discarded. The best results in my experience have followed when the canal is first cleared of any blood or exudate and followed by thorough cleansing with saline solution and alcohol, after which it is dried with sterile cotton, such preparation reduces to the minimum the chances for contamination; after this preparation we use a sterile Siegel otoscope to induce a negative pressure in the canal and in this manner aspirate through the opening in the tympanic membrane a bead-like droplet which does not overrun and pass onto the floor of the canal. The otoscope is removed and through a sterile speculum it is an easy matter to recover the droplet on a very fine sterile cotton tipped applicator. In cases of secondary mixed infection it is not uncommon to have the specimen reported as negative for streptococcus, and the reason is that the secondary infecting organism like staphylococcus albus will oftentimes submerge the primary infecting streptococcus and the latter organism will remain hidden until the secondary infection has cleared in the middle ear tract, after which it may be recovered. I have seen several competent otologists misled and follow cases of this character through to what they interpreted as a complete recovery from an uncomplicated, acute, suppurative otitis media and discharge them as cured, only to have a recurrence of the disease manifest itself in a variable period after apparent recovery. Nine cases of this character are included in this group.

The records show that in our military service 40 percent of the cases developed in the course of, or were noted to have developed at a period subsequent to an acute, streptococcic naso-pharyngeal infection. This percentage obtained in the face of two epidemics of measles, an epidemic of scarletina and the influenza epidemic and covers the period from November, 1917, to March, 1919. In civil practice this percentage is still greater, we will find it to be 61 percent in the cases recorded from March, 1919, to date. Confronted by this remarkable showing of the status of acute streptococcic naso-pharyngeal infection in relation to a disease which I have chosen to interpret as acute streptococcic osteomyelitis I feel justified in making this observation. An acute otitis media supervening as a complication in the course of an acute streptococcic naso-pharyngeal infection imposes on the otologist the responsibility to positively exclude the streptococcus as the possible causative agent of the ear complication, wherefore it is good practice to determine by culture the absence or presence of the streptococcus organism in every case presenting acute naso-pharyngeal infection, since this the streptococcus organism is the differentiating factor between acute otitis media and acute streptococcic osteomyelitis of the temporal bone.

CONCLUSIONS

1. Streptococcic osteomyelitis of the temporal bone is a clinical entity and is to be diagnosticated as such.
2. The etiological factor is the streptococcus organism, it may be of any type.
3. Recovery of the streptococcus organism from the tympanic exudate in a supposed case of acute otitis media is sufficient evidence to support the diagnosis.

DISCUSSION

DR. O. C. BREITENBACH (Columbus): Just a few words with reference to regional bacteriology. We are accustomed to associate with any inflammatory reaction of the middle ear the streptococcus of several types—the pneumococcus, the staphylococcus albus and aureus, diphtheroids, Pfeiffer's bacillus, and also, but in minor role, the bacillus proteus and the bacillus pyocyaneus. Some controversy exists at the present regarding the identity of the streptococcus mucosus capsulatus, some authors accepting it as identical with type three, pneumococcus. This discussion does not minimize the importance of this organism as an otologic offender. Suepfle some few years ago made a very careful analysis of several hundred cases of mastoiditis with especial reference to the bacteriological findings and took a firm stand in his assertion that staphylococcus infection was never a factor in the development of intracranial complications. Kerrison referring to the findings of this very able investigator asserts that this view is extreme and therefore incorrect, but that it serves to emphasize the infrequency of intracranial disease secondary to staphylococcus infection. He cites as a corollary that the streptococcus on the other hand is unquestionably responsible for a majority of cases of intracranial disease of otitic origin. The same author concludes by saying that even though we were to accept the conclusions of Suepfle as in the main correct, one must yet acknowledge that one cannot prognosticate from the micro-organism found in the tympanic discharge, the future course and severity of aural disease. This being determined quite as much by the patient's systemic condition.

And as a matter of fact we meet clinically with cases presenting an exceedingly severe type of inflammation and with extensive complicating pathology in which the staphylococcus is

the attacking organism and also with a very mild type of acute otitis media resulting from a streptococcic invasion of the middle ear. We must in every individual case not alone reckon with the virulence of the invading organism but also with the factors that determine vital resistance in the patient. I would hesitate to make the diagnosis of an acute uncomplicated osteomyelitis of the temporal bone on the finding of streptococci in the case of an acute otitis media, and I would think it presumptive to make the diagnosis of an acute complicated osteomyelitis of the temporal bone because of the evidence of a streptococcus infection demonstrated by smear in the case of an acute suppurative otitis media.

I accept as very radical the deductions of the essayist as it pertains to the findings of the streptococcus in smears from the middle ear. It is not necessary to try to explain away the virulence of streptococcic infection in middle ear infections in camps at the time of our last pandemic of influenza. Time will not permit the citation of factors that undermined the vital resistance of troops as a result of which a very high virulence was attained by invading organisms. Streptococcic pneumonia, therefore, was associated with an incidence of empyema that was startling. With an avidity for pericardial infection by this same organism, aspiration of the pericardium resolved itself into a routine proposition in many cases. And as we find more destructive pathology in other fields of medicine and surgery because of increased virulence of the infecting organism and lowered vital resistance in the individual, so in our otologic cases we suddenly were beset with a most acute symptomatology, sometimes baffling in the light of the secondary pathology *per extensionem* so graphically brought to our attention by the essayist.

I am inclined to look upon infectious osteomyelitis, and I believe authorities will bear me out, as an acute inflammation of bone due to the infection of bone marrow by pus organisms. The basic pathology is much like that seen in the furuncle and has been referred to as "bone furunculosis", although the process in the bone naturally undergoes modification because of the histology of bone determining a slightly different course from that of soft tissue. In the vast majority of cases the organism is the staphylococcus pyogenes aureus. In a few cases it is the streptococcus. The consensus of opinion favors the viewpoint that the streptococcus has a predilection for superficial infection of bone, producing therefore not a diffuse osteomyelitis but rather a primary periostitis.

Pathology of mastoiditis, as we have recognized it in the patient, centers itself in defective drainage following infection of the middle ear. There ensues the picture of an acute exudate associated with a leucocyte infiltration, the vessels become congested, the mucosal epiderm shows evidence of disintegration. The periosteum covering the bone depending upon it for nutrition becomes carious or the arteries in the mucosa become thrombosed and the blood supply is thus cut off from the membrane and periosteum as well as from the bone. Caries of the tegmen tympani and antri may readily carry infection *per extensionem* into contiguous structures. The question therefore presents itself, in what respect do the findings in acute osteomyelitis of the temporal bone differ from the picture of thrombophlebitis and the resultant osseous necrosis that we have all met clinically in the more destructive types of mastoiditis?

DR. ALBERT E. BULSON, JR. (Fort Wayne): The author of the paper is to be commended for the very careful way in which he has investigated his subject. However, I feel very much like Dr. Breitenbach does concerning the acceptance of all of the conclusions offered. We know that the extension of the infection depends not only upon the resisting power of the tissues but also as to whether the blood stream has been contaminated. So far as involvement of the temple bone is concerned, we all know that the anatomic peculiarities have a great deal to do with the possibility of extension of infection from the middle ear, and this is wholly aside from the nature of the infection. Sometimes the infection passes directly from the middle ear cavity to the antrum, but in other cases it meets with resistance through an obstruction in the *aditus ad antrum*. It is in this latter class of cases that it is quite possible for the infection to reach the temporal bone by means of the blood stream, but of course it can reach other parts equally as well. I am not prepared to accept the statement that in the presence of a streptococcus infection in the middle ear cavity there is always a blood stream infection, or that there is always involvement of the mastoid antrum and contiguous structures. Statistics show and I am sure that many of us have had cases in which the infection was of the streptococcus variety and yet those cases have gone on to recovery without operation. I confess that I always look upon a streptococcus infection as being a dangerous proposition, knowing that complications are more prone to occur than in any other infection. However, by carefully watching the progress of the case, including local manifestations, temperature, and blood count, we often may avoid operative interference. This does not argue that in a large percentage of cases there may be a blood stream infection. It merely argues that we are justified in being careful in resorting to heroic treatment. Of paramount importance is early and a wide incision of the drum membrane, absolute rest of

the patient, and watchful but intelligent waiting on the part of the surgeon with the intention of instituting operative procedures at the first positive indication of extension of the trouble.

DR. W. S. TOMLIN (Indianapolis): The Doctor has arrived at conclusions which I am inclined to think are very dependable as applied to the kind of cases which he has treated. However, I do not believe that it is quite proper for us to undertake to apply these conclusions in private practice. They do call our attention to a very important class of cases which may occur in private practice, and they should put us constantly upon our guard in cases of streptococcus infections.

I have observed the small and very restricted class of this acute streptococcus infection occurring in a family, in a school, or in an institution, and when you find a case of infection of the middle ear which follows the course to operation, and another case develops in the same household or school, you may reasonably expect it will follow about the same course. It comes back to the same point that has been developed —that the streptococcus is a species, and within that species we have types, and when you have a virulence in one case that has been contracted from another, the virulence may be quite similar.

This paper should keep us on our guard not to say that every case that shows an acute streptococcus infection should be operated without waiting. I think we should place ourselves in the position of the patient. If you had an acute streptococcus infection would you be willing to be operated within forty-eight or seventy-two hours, or within a few days' time, when there was nothing of a severe feature showing up? I think that is a point to be borne in mind.

DR. C. NORMAN HOWARD (Warsaw): I would like to emphasize the point of streptococcus infection entering the blood stream.

There comes to my mind the case of a patient who had a suppurative otitis media, left, with extension into the mastoid. The laboratory findings showed it to be a streptococcus hemolyticus infection. We operated and found pus around the antrum, in the tip of the mastoid and in the region of the lateral sinus. The sinus was uncovered. No thrombus was found.

During that week the right knee became painful and swollen and was aspirated. The hemolyticus streptococcus was found again in the knee. The right shoulder became slightly painful and swollen, but was not aspirated. The patient recovered without involvement of further structures by this streptococcic infection.

DR. HARRY BOYD-SNEE (closing): To cover one phase of the discussion let me point out that the middle ear tract is laid down early in fetal life, in the sixth month it can be identified as an anatomical entity and at birth the bony bounding walls are complete and are formed by fusion and folding of the pars squama and pars petrosa. The tract comprises the eustachian canal, the tympanic cavity and the antrum. The middle ear tract has a mucous membrane lining that is uninterrupted and continuous from the nasopharyngeal opening of the eustachian tube to the posterior wall of the antrum, and this lining membrane functions as a periosteum to the bony walls, and it derives its blood supply from branches given off the neighboring arteries. Intracranially the dura is applied to the inner plates of the squama and the petrosa and likewise functions as a periosteum to those structures. The vessels from the dura as well as those from the lining mucous membrane permeate the intervening cancellous bony structures and anastomose freely in the situation of the pneumatic and medullary spaces. In the medullary spaces we find the red marrow.

In every case in this large group, excepting one, the initial clinical manifestation of infection in the region was evidenced by the development of an acute inflammatory reaction in the lining mucous membrane of the middle ear tract and was recorded as an acute otitis media, the causal agents recovered by culture from the tympanic exudate was found to be the streptococcus. The gross pathology uncovered through operative wounds was characteristic vascular infiltration of the pneumatic and medullary spaces, with granulations and exudate; histo-pathological findings in the material removed were reported as showing round cell and leucocyte infiltration, thrombosis in the venules could be identified in specimens recovered in early operation before fibrosis and osteitis appeared as factors; cultures from the different areas explored invariably showed streptococci. On the foregoing anatomico-pathological and the bacteriological observations the specific diagnosis rests.

It has been impossible to estimate exactly the proportion of the cases in this group which should be classed as hematogenous infections that are to be distinguished from those cases in which the complication developed by contiguity in the course of an acute streptococcic nasopharyngeal infection. I can safely state that the greater number developed by direct extension from the nasopharynx. Clinical experience and autopsy findings will support this assertion.

In all the material utilized in this work the streptococcus organism has been identified as a Gram positive diplococcus recovered from cultures from which the pneumococcus has been excluded by test. It has typed variously as streptococcus mucosus capsulatus, streptococcus viridans, streptococcus pyogenes, streptococcus hemolyticus and streptococcus nonhemolyticus.

SOME PROBLEMS IN SYPHILIS*

R. V. HOFFMAN, M.D.
SOUTH BEND

The economic and social importance of syphilis is indisputable. It seems fair to state that the great majority of physicians appreciate their responsibility and obligation in this paramount issue of public health. But, as in most committees whose members are many, few participants take unto themselves the obligation of doing all of which they may be capable. One might state that every physician shares three great responsibilities: firstly, that to his fellow man; secondly, his duty to the advancement of medical science; and thirdly, his obligation to the insuring of his own success. The great prevalence of syphilis emphasizes the importance of the first and foremost obligation, that to his fellow men. Some time ago in attempting to determine the prevalence of syphilis in the United States, I consulted eighteen treatises written by nationally recognized authorities. Five placed the incidence of syphilis at 6 percent; three at 8 percent; three at 10 percent; two at 10 to 12 percent; and three upwards of 13 percent. The clinician whose estimate was 6 percent obtained his figures from a hospital clientele derived from the so-called "middle classes". The estimates above 13 percent were made in the poorer section hospitals, a considerable proportion of whose patronage was derived from the colored race whose rate incidence is probably double that of the white people. By taking into consideration the obtaining rates of incidence appropriate to each race and sex, and applying the rates in their relative ratios as indicated in the 1920 U. S. census, I have estimated that some 8,700,000 men, women and children of the United States have syphilis in some form. That is equivalent to approximately 8 percent of our entire population. Obviously these figures will not apply accurately to any single group of people, as the ratio refers only to the general average of many groups. However, I feel that one may conservatively consider that one person out of every twelve bears some form of syphilitic infection.

Our second great duty is the advancement of medical science in a manner that best conserves the health of the nation. To a considerable extent that may be done by lending our every effort to educate the public to the importance of demanding accurate diagnosis and adequate treatment. This may be accomplished by the profession's assistance for informing the public by means of press and other media of dissemination. Of equal and possibly more importance is our duty to prepare to render to the public the type of treatment which we advocate. If in our private practices we diagnose no more than one case of syphilis in every fifty patients examined, is it not probable that many luetic infections are being missed? The universal employment of routine Wassermann tests is neither practical nor necessary. The so-called "busy practitioner" can require every patient to strip to the waist, and routinely examine the eyes for the pupillary reflex and iritic adhesions; (2) the skin for lesions of undetermined etiology; (3) cervical and epitrochlear glands for enlargement; (4) the aortic valve and arch for murmurs; and (5) knee jerks. (The genitalia should be included if the history of genital lesions is obtained.) Such a routine may be satisfactorily carried out in two minutes. If the aforementioned regions appear normal, seldom will syphilitic infections be overlooked.

The Wassermann reaction is insufficient evidence for the determination of syphilis, in the absence of supporting clinical signs. Nevertheless it is advisable to treat many patients, where blood sera is "weakly positive", for the purpose of determining the etiology of the case—as indicated by the serologic response to antiluetic therapy. The Sachs—Georgi, Hecht—Gradwohl and other substitute tests are inferior to the Wassermann test. The principal claim made for the substitute tests is their faculty of detecting "weakly positive" serum reactions. The pseudo-positive reactions are frequently not apparently caused by syphilis, and they serve to obscure the diagnosis of the actual cause. The cholesterinized antigen is of value in determining the point beyond which intensive treatment may be discontinued. The luetin test is so unreliable that it should be discarded.

The third obligation, that of investing our efforts in tasks whose results are commensurate with our labor, may be discharged to an unusual degree of satisfaction in the treatment of syphilis. Despite the fact that no anti-luetic drugs of great value have been discovered since the advent of the arsphenamines, our efficiency in employing those drugs has been much increased. But we yet have much to learn concerning the efficient use of the drugs now available. Our therapeutic goal lies in the determination of the ratio of the maximum tolerated dose to the curative dose. The present standard dose—0.9 decigrams of neoarsphenamine per 150 pounds body weight, administered at weekly intervals—will probably give way to smaller doses administered at frequent intervals. The preliminary experiments which my colleague, Dr. Marcus Lyon, and I are carrying out on syphilitic rabbits point in that direction. It is probable that the larger doses may be preferable for the chronic infections where the spirochetes are

(*) Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

harbored deep in the lymph glands. It is difficult to understand the reasons why mercury is usually administered according to a pre-arranged schedule of dates and doses. Mercury not infrequently damages the kidneys, and if thus given despite the contra-indications it is liable to frustrate the further administration of the arsphenamines. The dosage and time for administration of mercury should be determined from time to time by the results of urinalyses and the condition of the patient. Iodides should be given in larger doses. The doses usually employed are far too small. It is seldom necessary to start on less than 60 to 75 grains daily, rapidly increasing the dose until symptoms of iodism occur. The arsenicals, other than the arsphenamines, have been disappointing.

The majority of syphilitic infections are susceptible to sterilization. The term "sterilization" is employed here in the sense of disappearance of manifest lesions, and the enablement of the "cured" individuals to beget non-syphilitic offspring. No evidence thus far adduced has shown conclusively that the so-called "cured" syphilitic patients still harbor spirochetes and may transmit the disease by sexual contact.

It is appropriate to call to the attention of the Indiana State Medical Association the remarkable work of the U. S. Interdepartmental Social Hygiene Board. That governmental organization has made appropriations to a large number of the country's prominent medical institutions for the purpose of developing better methods for the treatment of syphilis. As a result the following scientists — Engman, Hirschfelder, Reid, Hunt, Loevenhart, Ordway, Warthin, Winternitz, Hugh Young and many others—are working intently on problems of syphilis. Dr. Reid Hunt of Harvard, who worked with Ehrlich during the latter's search for an effective spirocheticide, has during the past year materially improved the methods for the manufacture of arsphenamine. It can now be manufactured considerably cheaper and purer than has hitherto obtained. Many other advances in the problems of syphilis have been made by these investigators who are cooperating with the Interdepartmental Board. Their results will be published for the benefit of the medical profession as soon as the discoverers have made adequate clinical application of their findings.

There is one problem in syphilis which I paroach with extreme hesitancy and indecision. I refer to the wisdom and necessity of attacking syphilis as a public health responsibility. It is apparent that the venereal clinics established jointly by the federal and state health organizations during the war, and since maintained in many communities, have made material inroads against the heavily infected populace. But what should be their future status? Should they be perpetuated? I know of no justifiable reasons why they should continue to exist as venereal clinics, *per se*. I do believe, however, that venereal clinics should be perpetuated as subdivisions of general hospital dispensaries. If there are no general dispensaries available to the community, then the establishment of a venereal clinic is perhaps justifiable, provided that it takes care only of the infected poor. In other words there are no particular reasons why syphilis should be handled differently from the various other diseases which affect a community.

Public health officials of several states (I have never discussed the subject with the Indiana officials, and do not know their attitude) have told me that federal and state participation is necessary "because the great majority of physicians treat syphilis inadequately, thereby jeopardizing the public health". If that be true, then it would seem befitting that the health officials conduct a campaign for the education of the physicians, directly by informational methods, and indirectly by influencing the necessary regulations in medical licensure. If our public health officials deem it necessary to handle the syphilis problem directly with the people, instead of through the physicians, it is apparent that such action must constitute a step forward in the direction of so-called "state medicine". The solution is up to us as private practitioners of medicine. If we continue in our present rut, state officials will be compelled to handle the menace to its public health directly through the people. If we believe that the responsibility is ours as private physicians, then we must prepare ourselves to treat the disease at least as adequately as it is now being done by the federal and state health officials.

DISCUSSION

DR. WILLIAM S. EHRICH (Evansville): There are a few things in Dr. Hoffman's paper which I would like to bring out a little more strongly, and a few things I wish to disagree with. His percentage of syphilis as applied to the North I think is rather correct, but as applied to the South with its immense negro population it is far too low. I was raised in South Carolina in the rice district where there were many negroes and I think it would be ultra-conservative to say that not less than 30 percent either have acquired or hereditary syphilis.

I think the most important problem in handling this disease is the early diagnosis, and there I can work in a few remarks about the clinic. I think the reason for the existence of these clinics is the very poor treatment that the ordinary physician gives to syphilitics. The important part in the treatment of syphilis, even more than in tuberculosis, is the early diagnosis. We all know that syphilis in the early stages is comparatively simple and is curable, but let it

go on until all the organs of the body become impregnated with the germ and it is a question whether it is ever cured. Now we have a great many physicians in our city, all of whom treat syphilis, but there are only four dark-field illuminators for the detection of early syphilis.

So far as the other laboratory methods go, I am a follower of the Wassermann reaction. I heartily agree with the doctor that the original Wassermann reaction is the most reliable. It is unquestionably an aid to our diagnosis and treatment of syphilis. A one, two or three plus Wassermann reaction means very little to me. A patient either has or has not syphilis. These little variations in reading are a matter of personal equation with the laboratory man, I think. If I am treating a person for syphilis and he is doing very nicely and his Wassermann reaction is negative, I think there is a chance that he has cleared up. If there is an accumulation of negatives over a long time I consider the patient cured. If the Wassermann reaction is positive I think the patient is not cleaned up and my treatment will vary as to whether the test is negative or positive.

So far as the treatment of syphilis goes, there was a time when we thought, and I believe correctly, that mercury cured syphilis. You take any case record today and you find that so many salvarsan injections are given and then so many mercurial injections and then a rest follows. I think that is a mistake. Even taking for granted that mercury will not cure syphilis, I believe that its administration will at least make the body an unfavorable culture medium for the spirocheta pallida; also the mercury will reach the organisms in lymph nourished tissues that the salvarsan will not, since the salvarsan is excreted within a short time of its administration and its effects are only noticed in the blood supplied tissues.

DR. GEORGE W. MCCASKEY (Fort Wayne): We are well aware that the Wassermann test is not specific for syphilis, but when patients have not resided in the tropics, it can usually be so regarded with certain slight reservations. I agree with the writer that too much importance cannot be attached to the exact percentage of inhibition, or as it is usually expressed, the one, two, three or four plus. The important fact is that there is something in the blood which, in combination with an antigen, combines with, "binds" the complement, to a greater or less degree, and thus impairs or destroys the hemolytic system. The same patient may show less at one time, and more at another, without any obvious change in his clinical condition. It is notorious that different serologists will get somewhat different results with the same specimen of serum. While a serologist is likely to make a negative report on the basis of a one plus Wassermann, the fact is that it may mean syphilis, and is a question for the clinician, rather than serologist, to decide. I have been watching these reactions in my own clinical laboratory for years and have many times seen a one plus Wassermann become a three or a four plus. It is well recognized that a syphilitic patient with a three or four plus Wassermann may, or perhaps usually presents a weakening Wassermann, but when it reaches a two or one plus, it should be, and I think generally is, regarded as evidence of a residual syphilitic infection, which indicates that the patient should not be finally dismissed, but should remain under at least intermittent observation over a long period of time, and should possibly have additional treatment. This is, of course, almost equally true when a negative instead of a weakly positive reaction has been achieved.

DR. A. W. BRAYTON (Indianapolis): It is largely dependent upon the impression you can make upon the patient as to the necessity of the persistent use of the old remedies, particularly mercury and potassium iodid where it is indicated. We should not discourage our patients by putting them in a position of believing they are incurable. We should brace them up and tell them the results of continued and perfect treatment. We should always be on the lookout for syphilis. It is deceptive and easily mistaken for other disorders and conditions. The prevention of it for those who are constantly handling it is the use of calomel and grease, one-third calomel and two-thirds grease, before and after, if there has been any opportunity for specific infection, because the spirocheta cannot get by those substances. If they were thoroughly used, according to the instructions given by the United States Army to the soldiers it would be a great benefit to the community at large and to those who are treating syphilis. We should insist upon these patients taking at least four courses of treatment a year. If we keep them encouraged and in good spirits, it will help a good deal, but we should keep after them. If they do not come to the office when they should, send for them, always impressing upon the doctors and the patients themselves the necessity of the long continued and harmless treatment. I think the majority of these patients by taking one-fourth grain of protiodid of mercury four times a day will have no bad effects. They may have a little looseness of the bowels for a few days and so on, but nothing serious. The new remedies have been of great help and assistance and we are persisting in their use, but the old ones are not to be neglected.

DR. W. A. FANKBONER (Marion): I would like to know whether there are ever situations where a repeated plus one Wassermann reaction

can be neglected, the patient showing a clinical cure through a long period of time, perhaps nine months or a year.

DR. ROBERT V. HOFFMAN (South Bend—closing): There are only one or two points about which questions were asked and I will answer those.

Concerning the North and South, I agree that that is the exact situation, but my figures apply to the population of the United States as a whole. It is a problem that the statisticians of the United States Public Health Service at Washington have been studying for a long time. They hesitate to give any figures, their general attitude being that probably 8 or 9 percent are infected. They cannot determine definitely. In the Washington University at St. Louis it runs almost 50 percent for the colored man and in our private practice it may be 3 percent, so they average it up as well as possible. The enlisted soldiers in 1907 ran about 15 percent, in the world war about 9 percent, and the average amount in Officers' Training Camps was about 3 percent, which balances the figures pretty well. [The figures of Love and Davenport (?) after enlistment were not over 3 percent.] The deplorable thing is that when people find some figures are not true, they are pretty apt to ignore all figures.

One negative Wassermann test, Dr. McCaskey, means little or nothing, as we all know. Later on that test may be found positive. The work of Ordway shows that in the work positive complement fixations the cholestrol esters are diminished and that does not necessarily mean syphilis. It means fat, and if the patient drinks lots of alcohol we may get a negative instead of a positive for new chemical substances are produced by the action of the alcohol on the fatty tissues.

I am sorry the question of the arsenicals was not taken up more thoroughly. I expected that to be discussed by the people who have used silver salvarsan and various other preparations. I recall that among the first articles published were those obtained from certain New York laboratories, containing a very glowing report on silver salvarsan. I had an opportunity of looking into the records to determine the basis from which he obtained his figures but they were not available—the conclusions were more or less of a "general impression". When such a good observer as Hazen reports that, while using silver salvarsan, mucous patches have appeared in the mouth, it makes one a bit skeptical. Experiments have shown that none of the substances so far produced have had quite the value of arsphenamin and neoarsphenamin. There is a general impression that arsphenamin is a little better than neoarsphenamin, but this has never been quite proved by anyone, despite the very intensive work of Kolmer. The fact is that anyone can use neoarsphenamin. If you get the arsphenamin solution into the tissues instead of into the vein, the patient will probably never return for further treatment, but if you get the neoarsphenamin into the arm by mistake the patient will not have such a serious lesion.

As to the question of rendering negative a persistent series of positive reactions, that is a problem. If you wish to give fifty or sixty injections of arsphenamin it may be reversed. Many of these are cases wherein the infection has not been wiped out, and the spirochetes still remain in the lymph glands.

It seems best to use the ice box method where the reaction will prevail much longer. It is hard to render certain cases negative. The important thing is that experience has shown that thousands and thousands of these patients after having been treated are married and have Wassermann negative children. These people live for a long time, feel well and have healthy children, and it seems to be the practical view to take, rather than be concerned with the few spirochetes lying dormant in the lymph glands.

WHAT THE GENERAL PRACTITIONER CAN DO IN OTOLOGY*

D. O. KEARBY, M.D.
INDIANAPOLIS, INDIANA

This paper is not written as a reprimand, but with a central idea, sincere hope and desire that an intense interest may be stimulated in otology, rhinology and laryngology by the profession at large. Not that every practitioner will, of necessity, need to become a specialist, learn a slipshod technique of operation, and thereby attempt some difficult procedure which will obviously fail of its purpose, but that every man practicing medicine will become acquainted with the simple instruments and normal anatomy of the ear, nose and throat, so that he will be able to recognize pathology early, at which time it is always simple.

To demonstrate our purpose, we will consider acute otitis media. It is an acute inflammation of the middle ear, a study of which must be made from its anatomical pathology and the allied structures, nose and throat, in order that subsequent complications may be expected and appreciated.

The complications are (1) acute suppurative and non-suppurative osteitis of the mastoid, (2) infective sinus thrombosis, (3) epidural abscess, (4) cerebral abscess, (5) cerebellar abscess, (6) diffuse suppurative labyrinthitis, (7) circumscribed suppurative labyrinthitis, (8) purulent

*Presented before the Eye, Ear, Nose and Throat Section of the Indiana State Medical Association, Indianapolis Session, September, 1921.

leptomeningitis, (9) meningitis, (10) chronic suppurative otitis media, (11) loss of hearing, (12) otosclerosis and tinnitus. The least of the twelve is a grave complication, and nine of them, when they are not recognized early and properly cared for, are in a vast majority of cases fatal. This battle line of the enemy should stand out, clear as a cameo, in the mind of any doctor when he stands on the other side of an acutely inflamed middle ear,

It has been well put by Newhart, when he says, "No branch of medical science is more neglected or none offers more promising results than study of ear diseases. Too long has the attitude of the average practitioner toward disease of the ear been one of passive indifference, confessed helplessness, or boasted ignorance." The charge for this blame should properly be laid to schools that made the doctor. Many of the schools, despite high classification, continue mediocre service to their students. The general practitioner's lack of enthusiasm in otology is due to this failure of the schools to provide sufficient and proper instructions in diseases of the ear, nose, throat and mouth. The head mirror and otoscope, and how to use them, are as essential as the stethoscope, and should be a part of every practitioner's armamentarium. Especially is this true in our particular climate.

Babies are absolutely unable to localize pain, and children up to ten years of age, unreliable. If it were possible that children could be relied upon to express themselves accurately as to pain, the affection of the ear should be discovered before pain has made its appearance. It requires but a limited amount of practice to be able to see and acquaint one's self with an ear drum and its half dozen landmarks. Any doctor could well afford, and he would derive satisfaction and pleasure to himself, besides being of inestimable value to his patients, if he would take three or four weeks' training in diagnosis in one of our numerous clinics. The tendency has been universal, among laity and profession, to neglect everything but the most obvious and painful ear affections.

Writing of this manuscript was disturbed just at this point by a man bringing his boy into the office suffering an intense earache, the result of snuffing water into the nose while swimming. The pain had been endured for ten days. The ear drum was bulging and red. Patient had increased temperature and a marked tenderness over the mastoid. Patient had been seen by a physician from the onset of the cold in the head. No ear examination had been made with light and specula. Patient was advised to syringe ear with hot water and instill some drops frequently. Patient left his physician and came into our office at the request of his dentist. Naturally the father was disposed to criticize the physician severely. This boy's ear drum should have been incised and the patient put to bed not later than when the pain began.

One especially trained in the diseases of the ear generally sees these cases too late to secure perfect results. To those of us who limit our practice to the special subjects, it is remarkable that neglect is as common in the intelligent and well-to-do as among the clinic patients. We emphasize that the laity are not to blame. If we hope to fulfill the great responsibility entrusted to us by the people of our communities, we must become teachers of health preservation, by laying aside a grave expression and dignified silence, which formerly cloaked a mass of ignorance, and teach in simple language to the laymen the structure, function and dangers common to the ear, nose, throat and mouth, in order that he can keep himself and family well. It is advisable that a small text book on the diseases, and how to prevent them, of the ear, nose, throat and mouth be placed in the curriculum of our common schools, and made a part of the prescribed course. In twenty years our communities would be intelligent, the family physician filling his needful and rightful place, with fewer specialists, more teeth and tonsils preserved, less suffering and greater happiness. However, under our present mismanaged system of impartation of knowledge we as doctors are pledged by the implicit faith placed in us by those who come for our service, to make an accurate and early diagnosis, anticipate and prevent complications, rather than offer a cure.

Before the Muncie Academy of Medicine recently, Dr. Joseph Beck read a paper emphasizing the need of recognizing the space of time that exists between an infection of the ear, nose, throat and sinuses, and the complicated end result. If the patient is seen early, which he would if he had been taught as referred to above, the disease would be recognized, complications anticipated, proper advice and treatment given, and we would have fulfilled our obligation and had an appreciative and well patient. Quoting Newhart again he says, "About 75 percent to 85 percent of all of our ear diseases are preventable, and at least three-fourths of them can be eliminated in a single generation. It is evident that the weight of responsibility lies on the general practitioner rather than the otologist, for it is the former who by his intimate contact with the family is able to give advice when it will be most productive of results. Especially in the community where there is no ear specialist, the physician must fulfill his public obligation by making himself familiar with the principles of otology and the necessary tests. He must detect even slight departures from the normal, and differentiate between lesions of the sound conducting and one of sound receiving apparatus. It is only by the very early recognition of abnormality and the immediate removal of all

active factors that any material advance can be made in combating the insidious affections which cause so large a percentage of deafness, often first noticed by the patient only after he has reached adult age. This point cannot be emphasized too strongly, for the average individual is, as a rule, quite unaware of any gradual oncoming impairment of his acuity of hearing until it is reduced to less than 20 percent of the normal.

VonTrolltsch has gone so far as to say that among persons over twenty years of age, when tested with great accuracy, one out of every three shows some impairment of hearing. Professor Koerner of Rostock made the surprising, but as yet unrefuted, statement that 4 percent of all deaths occurring in Prussia under the thirtieth year of life were due to ear diseases. On the basis of available statistics it has been conservatively estimated that there are in the United States today not less than 3,000,000 persons whose hearing is so impaired as to exclude them from many occupations, and to interfere, more or less, with their educational progress and social contact with their fellows. A single manufacturer of an electrical apparatus to aid the hard of hearing publicly advertises that there are in use 400,000 of his appliances. Within the past twelve months, in our own office, we did a functional test on both ears of 412 patients. One hundred and seventy-four gave as their chief complaint some disturbance of their hearing; 238 gave no complaint of impairment of hearing, nor were conscious of any pathology about their ears. Of these 238 patients who had no ear complaint, 40, or 16.4 percent, showed impairment of hearing. E. W. Kobler, in a paper entitled "A Survey of Ear Conditions in School Children," says, "The ears of 500 New York public school children were examined and it was found that 152 showed relative degrees of deafness."

The American Association for Hard of Hearing in tabulating 174 cases report the causes of deafness as follows: Measles, 6; scarlet fever, 13; meningitis, 13; diphtheria, 6; syphilis, 8; catarrh, 70; nerve deafness, 16; hereditary, 8; oto-sclerosis, 2; child birth, 1; occupational disease, 2; unknown, 29. The medical profession cannot escape the accusation that it has failed of its purpose when it is shown that 70 out of a total of 174 deaf people, practically 50 percent, is due to catarrh. What is catarrh? In the simplest terms the word spells contact of mucous surfaces somewhere in the upper respiratory tract and is preventable. To whom shall the layman appeal for information to prevent this awful waste other than the medical profession? The remedy is simple enough when thought of in a systematic way. First, a knowledge of the anatomy and physiology of the ear, nose, throat and mouth. The nose commands more attention as it is the outer guard or sentinel of safety. Given an infant with a normal respiratory tract, keep its nose open so that the air breathed passes freely, is warmed, filtered and moistened, the normal mucous secreted is evaporated by the air passing through, and this child should grow into healthy manhood without ear trouble or diseased pharynx or larynx. If hypertrophy of the adenoid occurs, it will have to be removed. The child's face will need to be protected from falls from beds and high chairs, the latter an evil which should never have been invented. In its young manhood and womanhood the modern athletics of basketball, football, and boxing should not be indulged. A paper could be devoted to the evils of these modern athletics. Heart, kidneys and central nervous system are impaired during training season and college contests. Just about the time the individual assumes responsibility in the business world he finds that he has catarrh, impaired hearing, frequent attacks of tonsilitis, rheumatism, and all the sequels of focal infection.

The duty of the doctor is primarily that of a teacher to his clientele and for examination of his patients he should possess a light, head mirror, tongue depressor, rhinoscopic and laryngoscopic mirrors, pillar retractors, and know the proper position to place his patient for examination. These can be easily mastered and obtained from any of the text books on ear, nose and throat. Keep the nose open and free to function, acute otitis media and mastoiditis will be reduced to a minimum, chronic catarrh of the middle ear and induced deafness will disappear. Hypertrophied and infected tonsils will not be met with.

No field of medical endeavor is receiving the attention that the upper respiratory tract is. The goitre specialist, heart specialist, genito-urinary specialist, internist, in fact the majority of patients are subjected to a scrutinizing examination by these men for focal infections about the nose, throat and mouth before forming a judgment or outlining a plan of procedure of advice and treatment.

A study of the nose internally includes septum, turbinates and sinuses. Both chambers should be equal. Septum should be straight and free of spurs, ridges or other deformities. Turbinates should hang free in their respective chambers. Especial attention should be paid to hypertrophy of posterior tips of inferior turbinates. If any of these are in contact by reason of hypertrophy, deviations, spurs or ridges, the condition is pathological and chronic rhinitis results. Tubal catarrh will follow with an end result of impairment of hearing. These abnormalities favor sinusitis by reason of obstructing outlets for drainage and aeration. We estimate that fifty percent of the hay fever and asthmatics

are due to mechanical defects in the nose. Our results show marked improvement and cures in about that percentage of cases.

One must know that the sphenoid and posterior ethmoid sinuses empty into the superior meatus and drain posteriorly into the naso-pharynx. The symptoms are stuffy nose, discharge into the throat, headache, and discomfort over the bridge of the nose. The frontal, maxillary and anterior ethmoids empty into the middle meatus and discharge found here indicates infection in one of these. The discomfort and pain usually point to which affected. Obstruction for air into any of these sinuses will cause a sensitization of the walls and produce pain. Ulcers and localized indurated spots in the nose suggest syphilis, tuberculosis or malignancy.

A study of the pharynx includes the naso-pharynx, oro-pharynx and laryngo-pharynx. In the naso-pharynx one will see the posterior tips of the turbinates, the posterior end of the septum, mouth of the eustachian tubes and the adenoid. The common pathological conditions found are hypertrophy and inflammatory.

In the oro-pharynx are the faucial tonsils lying between the anterior and posterior pillars, posterior pharyngeal wall, lateral pharyngeal wall, lingual tonsil at the base of the tongue, epiglottis and uvula. Inspection of the oro-pharynx always includes the mouth, tongue, cheeks, palate and teeth. The size of the tonsil is no criterion as to the pathology present. A large hypertrophied tonsil will be obstructive, but owing to its constant washing by saliva it will of necessity carry less infection than a small embedded tonsil. Attention must be called to adhesions of the pillars to the tonsils. Foci of infection are frequently hidden beneath a small adherrent pillar. With a pillar retractor tonsils can be easily expressed and direct inspection made of the contents. If the pillars are red, infection is present.

Lingual tonsil is a frequent cause of a tickling cough, due to hypertrophy and coming in contact with the epiglottis. This is more often a cause than enlarged uvula.

All these parts are subjected to acute inflammations. Any ulcers always suggest syphilis, tuberculosis or malignancy and should be watched carefully. Avoid caustics, simple ulcers heal of themselves in a few days.

The laryngo-pharynx is a continuation of the above down to the esophagus. It is subjected to the same inflammatory conditions.

The relation of the ear to all of these nose and throat conditions must never be lost sight of. Most of the ear conditions are direct continuations of inflammations elsewhere and should be examined frequently and carefully during any nose and throat affection, especially during exanthematous attacks.

A study of the ear includes an inspection of the auricle and external auditory canal. It should be remembered that the later is one and one-quarter inches in length, narrowest at the middle. The highest point of the floor is at the middle. Its direction is first upward and backward and downward and forward beyond the narrowing. To straighten, the ear must be lifted up. In infants, the upper and lower walls are in contact, due to lack of bony development. The drum closes the canal at an oblique angle. The knowledge of the obliquity is essential in determining abnormality of the drum and in incising. The outer half of the canal has hair. Furunculosis exists in this part only.

It should be remembered that the middle ear cavity is approximately the size of a grain of Indian corn, and the distance from the drum to the internal tympanic wall is but two to three millimeters. Hence bulging of the drum is produced by very little serum or pus. Any inflammation of the middle ear is secondary to tubal inflammation, which closes internal drainage, and the only means of escape of inflammatory products is by free drum incision.

Incision of the drum should be made unhesitatingly as the incisions heal promptly. The chorda-tympani nerve crosses the drum and may be severed in incision. Loss of taste on the same side of the tongue will be experienced, but is regained when the incision is healed.

Simple tests for locating impairment of hearing should be learned, so that the pathology may be located, whether in the conducting or receiving apparatus.

During the past twelve months we were consulted by 352 patients with various ear complaints. Our records of diagnosis show the following:

Auricle. Impetigo 3, sarcoma 1.

External Auditory Canal. Furunculosis 20, eczema 12, myringitis 2, foreign bodies 4, impacted cerumen 32, ruptured drum—traumatic 1, occlusion by an hyperplasia of connective tissue 1.

Eustachian Tube. Acute inflammation 26, chronic inflammation with hyperplasia 38.

Middle Ear. Acute catarrh 6, acute purulent middle ear 76, chronic catarrh middle ear 58, chronic purulent middle ear 30.

Mastoid. Acute mastoiditis with operation 46, chronic mastoiditis with operation 10.

In this series of 342 ear cases, 258 were complications that should have been prevented. The intelligence of the patients should have been sufficient to have induced them to have sought relief early, and of those who did consult a physician early the advice and treatment administered should have arrested the advance of the disease.

In the series of 56 operated mastoid cases,

five were bilateral; ten were advanced sub-periostal abscesses. There were five cases of lateral sinus thrombosis, three of which were of long standing when seen. The three promptly died of general septicemia. Two were in the hospital under close observation when the pathology manifested itself. Both made uneventful recoveries due, we think, upon recognizing sinus thrombosis, and operating immediately after the first chill and sudden rise of high temperature. Three cases developed tempero-sphenoidal brain abscesses, two of which were in the lateral sinus group. The two that were moribund when admitted to the hospital died, one due to a rupture of the abscess and pouring of pus into the ventricle of the brain. This case did not have a thrombosed sinus. The second died from general septicemia, the abscess was evacuated. In the case which was in the hospital and carefully cared for, the abscess was evacuated, and the patient made a good recovery. One case died post-operative from meningitis. She came to operation six weeks after being advised that a mastoidectomy was necessary. Meningeal irritation was present at time of operation. Any one of these seriously complicated cases could be recited in detail, with much interest to this section, and stimulate discussion of great importance to us as a body of specialists. However, that is beyond the intent of the purpose of the paper, and I have incorporated a perusal of them only to emphasize that they really exist and are frequent in occurrence. The results obtained in the two successfully conducted sinus thrombosis cases demonstrate that one should not delay in suspected sinus thrombosis to operate the sinus upon the advent of chill and high temperature. To wait three or four days to make sure is depriving the patient of an almost surety to live and reducing him to a doubtful chance. Of course you will understand that in the cases we are under most grateful obligation to the internist, neurologist and ophthalmologist. Without their co-ordinated skill and knowledge we should have been tremendously handicapped.

In our office we have practically come to the conclusion that mastoiditis, like appendicitis, should be operated upon diagnosis. In my student days I was taught watchful waiting in appendicitis. The laymen know better now. The complications in mastoiditis are equally grave, unoperated the fatalities as great. Shall we be laggards in our specialty? The general surgeon cannot announce edicts for us. Years of improper teaching has led the general practitioner and layman to look upon mastoidectomy as an operation of such serious import that it is done only when imperative. This idea is wrong. The operation is relatively simple, and safe in skilled hands. Once that a patient has mastoiditis he is as sure of a recurrence as the patient in the appendix case. The operation is of no greater risk.

DISCUSSION

DR. GEORGE W. SPOHN (Elkhart): After thirty-five years' experience I naturally have different views than I had when I was the age of the essayist. I agree with Dr. Kearby that the general physician should be better prepared for ear work. As it is he does all kinds of work, even operating upon anything that presents itself. Most specialists practice the art because it offers better opportunities for *good work*. It would seem that their field would be small, and yet they realize that one cannot cover the whole subject of medicine and do justice to the patient.

I hope that no general man will treat an ear case but will refer all such to the specialist, not expecting any compensation from the specialist for so doing. There are some physicians who will attempt to treat eye and ear cases, not knowing how many eye cases become blind and how many ear cases become wholly or partially deaf because of wrong first treatment.

I agree with the essayist that many cases of otorrhea might be avoided if handled rightly, but is the general practitioner to blame for an infection that has passed up the eustachian tubes? Politzer tells us that all cases of acute ear infections carry with them an involvement of the mastoid. From what I have seen in my work the trouble lies not so much with the general physician as with the parents. Though it may be an offensive subject, yet it is a fact that very few infections ever pass up the tubes if the nose is rightly blown. If our welfare stations and teachers would teach children how to blow the nose, there would be very few cases of otorrhea. You will not agree with me upon this question, but it is a question of physics, pure and simple. If one studies the mechanism of the ears and teaches the physiology of the ears to the children, there will be fewer cases of colds, nasal discharges and otorrheas.

DR. ALBERT E. BULSON, JR. (Fort Wayne): In the main I agree with the essayist that a general knowledge of ear affections is desirable, and yet I am satisfied that the old saying, "a little knowledge is a dangerous thing," is very true when it comes to the recognition and treatment of ear diseases and especially those that lead to serious consequences. The trouble of it is, the man who has had only superficial training and a limited experience is not very qualified to decide when a condition is serious or not. A condition that is very serious or may lead to serious consequences may appear to be very simple to the average practitioner and vice versa. However, I do believe that every physician should be able to differentiate between a normal ear drum and one that is congested, though even

in attempting that I have seen some serious blunders made by well trained general practitioners who really have had considerable instruction in the use of the head mirror and speculum and the recognition of acute inflammatory conditions of the middle ear. It has been my observation that the very best general practitioners do not rely upon their judgment at all, though they have sufficient training to recognize the possibility of ear complications as being a factor in producing certain symptoms, and in justice to the patients as well as themselves they call a specialist to their aid. To me the most important thing is that the physician should recognize the possibilities of the ear trouble rather than be able to recognize the ear trouble itself. Already we are burdened with too many pseudo specialists, and when these pseudo specialists make almost criminal blunders, how are we to expect the general practitioner to do any differently when he has even less training? I do not agree with the essayist in the assertion that the general physician should be able to make functional tests of the hearing and differentiate between diseases of the sound conducting and sound perceiving apparatus. He will serve his patients best if he recognizes his limitations, and while I am heartily in favor of educating the general physician up to the point where he can distinguish abnormal ear conditions and their possibility for harm, yet I think that is as far as his attention to the patient should go if the patient's best interests are to be served.

DR. GEORGE F. KEIPER (Lafayette): As Dr. Bulson has just stated, the best equipped men in general practice will not treat the cases cited in the paper. Permit me to give a leaf out of the experiences encountered by myself. We have some practitioners in our city who do a great deal of practice among children. They know what many another does not seem to know, that a fever in a child may be due to an incipient otitis media purulenta. In such an emergency they shift these patients to the otologist, who finds the diagnosis correct as a rule. The ear drums are opened, as ear drums should be opened, and the fever promptly subsides. The child promptly recovers with no ear complications. How often do we see the other condition of affairs where the little one is allowed to suffer until the ear drum ruptures itself, and in the meantime an acute mastoiditis is the complication.

But we are in a poor way to advise our brother practitioner what to do until we clean house among ourselves. It is a notorious fact that of all the men and women practicing in these specialties, three out of every four are not competent to practice ophthalmology and otolaryngology, and until we clean house among ourselves the general practitioner will not take very much notice of what we may say or write for his or her edification. But if we approach this subject in a becoming manner, humbly, willing to show the profession how to treat these patients and what it means to neglect the means at hand, I am sure that they will then be ready to give the attentive ear, and their patients will profit thereby.

There is coming—and it must come—a standardization of these specialties. It has already been instituted in ophthalmology. We now have the National Board of Ophthalmic Examiners. We are hoping that this day is dawning in otolaryngology, and, in fact, efforts are now being made to that end. With these boards in existence it will be but a matter of time until every one essaying to practice in these specialties must appear before these boards to establish competency. At the present time it is voluntary, so far as the Ophthalmic Board is concerned, but to date many have been willing to submit to the examinations of the Board to determine their fitness. When all this is accomplished the general practitioner will regard these specialties with more favor. The postgraduate course of six weeks to three months must disappear before the seminar of a year at least for preparation leading to the practice of ophthalmology or otolaryngology.

DR. C. H. MCCASKEY (Indianapolis): I think it is generally true that the average medical school is now trying to teach its students the fundamentals of otolaryngology—not to make them practitioners of this particular specialty, but they are trying to make them understand the normal, as nearly as possible, and in doing that they are usually taught to find the pathological. Students are taught something about the inspection of the normal ear. These men, when they go out from school, do not wait until a child has a bulging ear drum. They find it before it begins to bulge, when it begins to redden—for instance, in scarlet fever, or measles, or any other acute, infectious disease of childhood.

I am perfectly willing to admit that we need some housecleaning among ourselves. There is certainly a tremendous feeling on this. My personal opinion is that any practitioner of medicine should be quite as well acquainted with his head mirror, and his instruments for examining the ear, nose and throat, as with his stethoscope. The man who is doing the whole field of medicine is not as keen with his stethoscope, perhaps, as is the man who is listening to the heart day in and day out.

My plea is not that every practitioner should be an otologist, but he should know enough about it to recognize the pathology early, and he is the fellow who will recognize the normal condition and the pathology that follows—infection or what not. The man who cannot do

this is dangerous. I think we can prove that in our own clinics and hospitals.

Somebody said at Kansas City a year ago that the young undergraduate should know enough about otolaryngology to make him a good interne. Practically all of our boys go through hospital training and if they have had enough teaching of otology to make them good internes they will know a little something about early diagnosis of these ear troubles, and if they are fairly conscientious they will not do the wrong thing.

DR. M. H. KREBS (Huntington): I desire to second Dr. Bulson's statement in regard to those men who don't know very much. At the same time I want to say that I do not think that we should condemn some of the general practitioners who are doing ear work. Since the war a number of the men who were in general practice have found that they were unable to continue their general practice. They saw the men who were doing specialty work, and they immediately went to schools which claim to train men in specialties in two to four weeks. I really think that the necessity for doing house-cleaning among ourselves is owing to the fact that so many of our men who were in the general practice have gone into this special field of medicine, and not being properly trained they give us as much or more trouble than the general practitioner. I have great respect for the general practitioner.

I can cite one case where a general practitioner had as a patient a little boy with an intermittent fever. He called me into the case. I examined the boy very carefully, but could not establish any diagnosis of mastoiditis, and the x-ray pictures didn't show any mastoiditis. Yet the child went right along with fever, and the doctor kept insisting that there was trouble somewhere, and he believed it was in the mastoid. Finally we went in there, and both mastoids were involved. There was a purulent infection of both mastoids. So I have great respect for the general practitioner, and I want to take issue with Dr. Spohn in his assertions.

DR. D. O. KEARBY (closing): I qualified the paper early by saying that while all men may not learn the technique of operation or treatment, every man should know enough so that he will be able to recognize a condition, and then select somebody that is capable of taking care of it.

My experience in Indianapolis with our pediatricians is that they are good diagnosticians, and I have not had the sad experience of having to follow where they have attempted to open an ear drum. If they do that kind of work, I don't know it. My friends who are taking care of children, when they find otitis media, recognize it, and call upon some of us to help them out in the treatment.

When I was a medical student twenty years ago, I was taught scarcely anything about the ear, nose or throat. As I practiced medicine, my patients became my friends, and I soon realized that I should be able to recognize diseases common to the nose, throat and ear, not to be able to do a mastoid in order to make a few dollars, but to be able to recognize the condition of the ear drum before a mastoid complicated it; that I should know sufficient about the nose to recognize that chronic rhinitis is due to malformation of some sort, and refer the patient to somebody who could take care of him properly.

In this paper no blame has been attached to the family physician anywhere. It was written in hopes that it would stimulate him to carry in his grip that sort of equipment, so that in the treatment of ugly, infectious diseases, of which we have so many, instead of depending entirely upon the stethoscope to listen to the lungs, and the thermometer to get the temperature, he will study the ear drum, not with the idea that he is going to open it, but to know whether it is, or is not, infected, and thus save the patient from a complication.

My plea in the paper, gentlemen, has been that every practitioner should have sufficient knowledge of, and be sufficiently acquainted with, the simple instruments that we use, to use them properly, make a diagnosis early, and then correct the condition before a complication arises.

SAND BUR IN THE LARYNX

REPORT OF A CASE—ENDOSCOPIC REMOVAL

GEORGE F. KEIPER, M.D.

LAFAYETTE, INDIANA

Apparently the presence of sand burs in the larynx or trachea is of infrequent occurrence. Reports of such cases in medical literature are very rare. At the last meeting of the Section on Laryngology and Otology of the American Medical Association, Dr. H. Marshall Taylor of Jacksonville, Florida, read a paper on this subject. He reported a series of nineteen cases, in sixteen of which the burs were removed from the larynx, and in two from the right bronchus. But very few were able to participate in the discussion which followed, owing to lack of similar experience. Even the high priest of endoscopy in this country, Dr. Chevalier Jackson of Philadelphia, had never extracted such a foreign body from the tracheal tree, and he has removed about everything else along this line.

From private conversation subsequently with a large number of the men present at that meeting, I learned that none of them had ever encountered such experience. Yet sand burs are found all over the country wherever sandy

places abound. After thirty years of laryngological experiences I never had such an experience either. However, since that meeting it has been my good fortune to encounter such a patient and to remove the sand bur endoscopically.

On August 8th this year I was asked by Dr. George R. Clayton of this city to remove, at St. Elizabeth's Hospital, by the direct method, a sand bur from the larynx of Miss Mabel L., age 16, of Medaryville, Indiana. Her general condition was otherwise normal save for a temperature of 100 degrees F.

Two days before, while playing with the sand bur, in an unguarded moment she placed it in her mouth, and a sudden inspiration caused it to be carried into the larynx. It lodged on the right vocal chord.

Her family physician attempted its extraction unsuccessfully by the indirect method. Dr. Clayton likewise failed. When I looked down the throat with the mirror it looked so easy that I attempted it thus and failed. I have vowed several times that I would never even attempt the indirect method again.

After the failure to extract it indirectly, we laid the patient on the table with the head extended over the end of the table, and supported by Dr. Clayton. I then inserted the Jackson speculum, caught up the epiglottis and gently entered the larynx. The sand bur presented beautifully and with the tubular forceps I grasped and removed it, a maneuver taking only a couple of moments of time. I exhibit the specimen to you to show you what a dangerous thing it is to have in one's breathway.

Medaryville is situated in the northwestern part of Indiana, in a sandy region which becomes much more so as the cities of Gary and Michigan City are approached. Sand dunes abound and these grow sand burs in great abundance, the ground being matted with them.

Taylor in his article referred to reviewed this subject of sand burs in the air passages quite thoroughly and finds eighty-five cases in the literature and otherwise. Seven of these had "successfully run that gauntlet consisting of the epiglottis, upper laryngeal orifice, ventricular bands, vocal cords and trachea to become a foreign body in the lungs". In other words these organs are the watchdogs of the tracheal tree. Of the eighty-five cases, six resulted fatally. One of these was a patient of Taylor's.

In the series reported by Taylor, the oldest was 22, a woman. The others were less than twelve years of age, seven being between the ages of 8 and 12. The youngest was 3 years of age. My case was 16 years of age.

My case also confirms Taylor's observation that an exudate is thrown out over the bur which may be so excessive as to simulate diphtheria in the larynx.

DISCUSSION

DR. D. W. LAYMAN (Indianapolis): There is one point in this foreign body work that I wish to bring out, because I feel that a great many physicians who are not acquainted with bronchoscopy and esophagoscopy look upon the general conditions, physical conditions, anatomical conditions, the manual dexterity necessary to remove foreign bodies, etc., just about the same whether the foreign body be in the upper respiratory tract or in the esophagus. This is a common error, and the physicians should be taught that these conditions are entirely different. In the first place, in the esophagus you are dealing with a collapsed tube. In the upper respiratory tract you are dealing with the upper part of the esophagus, which is supplied with muscles, and the musculature there produces spasms more marked in some cases than in others. In dealing with the esophagus you have a tube that is more apt to rupture in manipulation. You have not that sense of sight and touch that you have in the more open tubes. The upper part of the esophagus being open and having larger spaces, the foreign body is more apt to be hidden in the folds.

On the other hand, in the lower part of the esophagus, you might say from the thoracic aperture, you have a negative pressure. If the body has passed the thoracic aperture, it is apt to be turned downward.

In giving a general anesthetic for foreign body work in the esophagus, the foreign body is more apt to pass and be forced downward than is a foreign body in the upper respiratory tract, because of this relaxation and this muscular spasm in the upper part.

DR. ALBERT E. BULSON, JR. (Fort Wayne): I congratulate Dr. Keiper upon using the direct rather than the indirect method in removing the sand bur from the larynx. The time has come when we ought to get away from the idea of removing foreign bodies from the larynx by the indirect method. Direct laryngoscopy and bronchoscopy is now so well established and is such an excellent procedure that it ought to be adopted by every operator.

Inspiration of sand burs evidently is rare. I have seen one or two cases of sand bur in the throat but not in the larynx. In one case there was great suffering from spasms of the glottis. The interesting feature of these cases is that for the most part the foreign body can be removed without giving a general anesthetic, and that is a matter of great importance.

DR. ADAM B. KNAPP (Vincennes): Twenty years ago I had the fortune, or misfortune, to see a case of sand bur in the larynx. The mirror showed the sand bur lying against the lower

surface of the vocal cords. It could be seen just as plainly as if I had had it in my hand. I did not make any effort to remove it, as all surgical procedure was refused. The young girl carried the sand bur for about twelve months, and was able to speak in a whisper, but not above a whisper. At the end of that time she had a spell of severe coughing, coughed the sand bur out of the larynx, and brought it to me, to show me that she had delivered it. The spines of that thing were just as long and just as hard and firm as the day she inspired it. What happened to bring it out I don't know.

DR. GEO. F. KEIPER (closing): I used a local anesthetic, a four percent solution of cocain swabbed on the pharyngeal membrane only, none in the trachea. It is advisable to work under a local anesthetic. General anesthetic is very dangerous, and should be avoided.

I have searched the literature for similar cases, using Dr. M. A. Goldstein's Review published in the *Laryngoscope* every April. I ran that way back and could find no record like Dr. Taylor's, and mine. Sand burs are very prevalent and surely many other physicians have encountered similar experiences which they should record for the benefit of the profession in general, and their patients in particular.

As to endoscopy in general: The indirect method is out of date. The direct method is so much better if you know how to use it. But be sure that you learn it first under careful tutelage and by the dint of much practice, one way or another thereafter.

A MEDICAL SERMON*

FREDERICK E. JACKSON, A.B., M.D.
INDIANAPOLIS, INDIANA

The time limit cut out most of my sermon, but I shall state my text from the 30th verse of the 15th chapter of the Gospel according to St. Matthew, who said: "He that is not with me is against me, and he that gathereth not with me scattereth abroad." For ten years I have preached this sermon, and tonight I preach it again. The subject is more vital tonight than it was ten years ago and unless the medical profession as a unit meeteth in my name it scattereth abroad.

I hope I am not hyperesthetic! I hope I am not an alarmist! I hope my vision is clear when I say I see in the distance the dark cloud of socialized medicine still coming our direction, gathering as it comes many blind and selfish groups and individuals.

Let us first consider what changes have taken place, what changes are taking place, or are about to take place, which changes make it necessary, desirable or unavoidable to socialize medicine. Up to the last generation, or about, the pauper was perhaps the most important practical question with which the medical profession had to deal. The old English idea that charity was more or less a disgrace prevented to some extent the growth of socialistic ideas. Now days when charity working has become as distinct a profession as law, is it any wonder our ideas are gradually being moulded in favor of the state's supervision of poverty and charity? The growth of industrialism with its increasing competition has made it necessary to have someone look after the sick and maimed so that the grist from the mill will not stop. The harangue for efficiency has attracted the attention of the employer, the economist and the sociologist, and has helped to give birth to the social worker. The social worker by clever propaganda has not only evolved and refined her position into a profession of extreme honor and necessity but has been seized upon by medical socialists and made into willing tools for the sowing of seeds of socialism in medicine. Modern medical education, vague ideas in regard to the relationship between the medical school and people, rapid strides of medical science, especially in regard to the causes and prevention of disease, have added impetus to the campaign for centralized, nationalized and bureaucratic control of medicine and of the medical profession.

Medical education is now such that the graduate refuses to go back to the country town where he has few luxuries in life and small opportunity of practicing experimental medicine according to the latest theory from the laboratory.

Thus, paradoxically, modern medical education has given the honest and dishonest propagandist the erroneous idea of a scarcity of physicians. These reasons, together with economic factors, gave Julia Lathrop the chance to say to the congressional committee in charge of the Shephard-Towner bill, "Why put this work in the hands of an already overworked class when there is now a scarcity of physicians in the country, and when women social workers can do this work as well? This is a social problem." We know she was uninformed or purposely misrepresenting; and as for a social problem, I have never seen any sickness or injury which was not a social problem, and will be, so long as there are any relations between members of society.

The world war with its rapid destruction of man power and material wealth has promoted the desire for a flawless machine to replace those losses, to prevent future losses, and to be prepared if such future losses become necessary. With such mixed altruistic and selfish purposes existing, much confusion of action and thought

(*) Read before the Indianapolis Medical Society—The Medical Society of Marion County, March 21, 1922.

exists. Such mixed purposes and confusion has led to the jumbled up ideas of socialism, bolshevism, communism and other isms of which socialized medicine is one of the wobbly wheels. This reminds me of the old champion mower. This machine in place of the straight pitman rod had a complex universal wobble gear to give cutting power at any angle. It was a wonderful selling point, but it wouldn't work. The end nearest the power cut high, and the one farther away cut low, and there was no chance to exchange ends. In like manner socialized medicine, with a high and low cutting end, is only a selling point. The agents are many, various interested individuals and groups who fail to say when selling that when a man is underpaid, under compulsion, or his initiative taken away from him and vested in a high cutting end close to the power he refuses to do good work.

Faculties of medical colleges are apparently not satisfied with their positions as salaried men with the privilege of private practice brought to them by the advertisement of their position, but in many instances covertly or openly attempt the building of state machines with themselves as the respective heads, relegating to private practitioners the honorable position of reference physician to the people. You are doubtless aware of what was attempted in Michigan by the state medical school. You have seen with what poor grace those men backed out of their position. Dr. Hugh Cabot is reported to me as having said one of his reasons for coming to Michigan was because that state would be next to take up state medicine. You have heard what Cornell and Harvard have done, what Buffalo is doing and you can surmise what may be done in other states when the time seems opportune. What these schools have done can easily be done by any organization financed by state taxes or by a philanthropic endowment. It is needless to discuss the effect upon the economic stability and development of competing industries if some were able to endow themselves through charity or the state. At Cornell we have a charity endowed clinic in competition with private practice. In Michigan we had the attempt of a state endowed institution in competition with private practice. I ask you what is the difference between state endowed industry in competition with private industry and between a charity endowed clinic, or a state endowed institution or a charity or state subsidized doctor in competition with private practice?

The recent enfranchisement of women has given to that sex an enlarged idea of importance in government. This idea, born of the maternal instinct, seeks its outlet naturally through state medicine and other socialistic schemes. Mothers are making their appeal through pictured useless and avoidable suffering of maternity and of their babies. Those who are not mothers, and those hopeful women who cannot be mothers, make a dangerous appeal to sentiment, and you have a hard time beating sentiment. These women are dangerous because you never know what they will do. Their rhetorical figures of speech are treacherous. They say all people are learning how much misery sickness causes and are demanding the decrease of misery. They say the state cannot afford sickness, must have health, no matter how it comes. They tell how advanced medical men preach it, that business and insurance men say it will pay, that social workers ask why we go on building institutions, that people are tired of being lied to and of being fooled, that it is a lie that anyone who wants medical attention can have it, that the patient no longer can afford to pay what the doctor has to charge, that if the doctor does not find the way by which expert work can come within the reach of all, they will. You have been aware for some time of the effect of the impression slyly left, "we have something for you which you can't get anywhere else."

Nurses in industrial nursing, school nursing, public health nursing, state medical school propaganda work, have helped to spread the glad tidings.

Compensation laws with all their disagreeable features were passed while the medical profession stood in wild-eyed rebellion saying, "they can't do it", but they did.

The increased cost of sickness to the individual brought about by the increased cost of medical diagnosis, nursing, hospitalization, has led to a demand for lower costs and has found its answer in the propaganda of the wily physician who has made a failure of practice, the nurse who despises private case work, the social worker who draws a good salary for attacking the medical profession as the least dangerous opponent and the most obvious person on the scene, the faddist engaged in the noble profession of uplift work, the uninformed laborer who thinks he is going to boss the doctor, the politician who thinks he is going to stay in office by offering the people something for nothing, the lodges which offer much for little, and the poor blind innocent who knows only enough to turn her head parrot-like and squawk state medicine.

We also hear occasionally from the women members of the profession. Dr. Philbrook of Lincoln, Neb., (I apologize for quoting her), says that no male member of the profession is fitted for treating women and children, further saying in regard to the Shephard-Towner bill, "seriously it is a matter of rejoicing that at last in the march of social and political evolution a public fund for the amelioration of maternity and infancy is to be administered by persons

possessing not only the highest social and medical training but also the inherited instincts of age long motherhood". I quote this to ignore it, but at the same time to call attention to what silly prattle can be used for propaganda which may with unthinking people cause an unwholesome influence.

The Rockefeller Foundation, rich in money which you and I have helped create through our forced tribute to a system not to our liking, has for the purpose of creating a school of public health given millions to Johns Hopkins, whose purpose we can only guess through its attempt at controlling and regulating fees. Such foundations, dangerous in a democracy, may, through gifts to institutions, mould public opinion.

New York State in its legislature has just killed a bill to meet the requirements of the Shephard-Towner bill. Such bill will be introduced in other legislative assemblies. Other bills in regard to medicine and health are to come up in the various legislatures and in the next session of congress.

I have briefly stated past, present and future movements whose purpose was or is to mould public opinion in favor of some form of state medicine. I understand you were told state medicine is dead. In the light of what you are reading every day, of what you are observing; in view of the fact that some of the officials of the A. M. A. are nasty when their vision or purpose is questioned, and that the A. M. A. is to discuss its attitude at the coming meeting; in light of the fact that a recent communication to me from Samuel Gompers says the American Federation of Labor has never stated its position but will have a committee report and discussion in June at its Cincinnati meeting—do you believe state medicine is dead? I do not, and I beg of you not to believe it. Let's not be ostriches, sticking our heads into the sand. While we sleep, or fume and fret with each other over petty affairs, state medicine is insidiously creeping on, and some day we shall awaken to find a new system with which we had nothing to do with the making. No, it is not dead, and I, for one, shall not rest until it is dead and buried and its vault so closed that no social angel can roll the stone away. Why does it not die? Does a bona fide health problem exist? It either exists or the socialists, social workers and bureaucrats are making a concerted attack upon the medical profession in the creation of a new division of labor from which they expect to derive many good paying jobs. I cannot quite bring myself to believe that it is merely a conspiracy for the creation of salaried jobs for women and men who hold themselves above standing behind ribbon counters, and yet it is sometimes not clear if these self-styled promoters of the evolution of society, both lay and professional, are really interested in health, why they make their chief attack upon the medical profession instead of upon the economic system, the legal system, drugstores, housing, Christian Science, chiropractic, etc., unless it is because they see in the medical profession the most weakly organized opposition, and because it is only the medical system which the social worker intends to socialize and supervise.

My ten years of experience with social workers of every known classification has led me to believe that the social worker hopes sooner or later, in a state system, to control and supervise a great part of the medical profession and practice. It does not touch the situation for the medical profession, drunk in its own conceit, to sleep soundly on, oblivious of the changing, seething mass of humanity. If we were living and dealing with nobility, we might justify our attitude of noblesse oblige. But society still exists much in the animal stage.

I believe there is a problem or condition existing which demands the earnest thought and analysis of the medical profession. The question of the poor, which we have had always, is not now the only one to be considered. Our social, economic, industrial organization is no longer simple. So now, with the wonderful growth and complex development in our industrial system, with millions of people, with the development and evolution of our various systems in mass, losing sight of the individual, with the increasing costs in hospital, medical, surgical, diagnostic and preventive care, with the newer ideas as to the value of human life and good health, the question is—do the existing measures and means adequately fulfill the demands? A great many individuals and organizations do not, and we shall see briefly on what basis they have tried to solve the problem. Insurance companies, organized for profit, use the doctor merely as a servant in the formation of profit and their solution has not been encouraging to the medical profession. Lodges offer contract practice at a fee, usually so small the doctor shirks thorough work to the patient. Charity organizations offer contract practice or ever increasing burdens. And the howls of the medical profession from this burden has placed a big stick in the hands of state medicine advocates. These advocates are quite solicitous of the welfare of the profession. They are saying it is not right for the doctors to have to care for all these people for nothing. They know the alternative is a state system with many good social jobs. We know the state rarely pays well where it should. We know the doctor would be underpaid, subject to call day or night at the whim of the patient or social worker.

and be subject to fines and control. Regardless though of how humorous this solicitude for the profession's well being is, it is telling, and the medical profession will sooner or later have to decide between the two or offer something constructive. Social service and public health nursing associations are really not so much concerned with the system just so it promotes their growth. They champion the cause of the patient as against the doctor. The chief fault here lies with the doctor or profession for not having enough constructive lime in its constitution to compel right relations. Industrial organizations are profit seekers with a desire to subordinate *everything* to industry. The U. S. P. H. department, in accepting rich and poor in its clinics, is developing a system detrimental to the profession and ultimately to public health.

Now what is the medical profession to do? Are we to be stampeded or magnanimous? Are we to listen to the words of the wily, and be deceived into believing there is no problem and no use to act or worry? I think we Americans are often inclined to live in an atmosphere of illusion. At any attempt of one to pierce this canopy of illusion we shrink. Especially as doctors of medicine, perhaps through the example of the A. M. A. officials, we assume an attitude of "the king can do no wrong". But illusion is not successful and if we do not bring ourselves into the light, and if we leave it to others, we will be groping and singing the old song, "Lead Kindly Light".

The social cry is now for good health, that it is only one of many human problems, and if we do not tackle it, industry through the help of hundreds of interested agencies, private, state and municipal, will—for at the present time they have their eyes riveted upon this problem and are so charmed they cannot remove them. We must become the charmers. We must direct both for the profession and people the trend for health education, and in many respects reverse the present trend. Instead of the Prussian idea, God state, we must substitute the more correct idea of a vague term standing for that which should be but often isn't. Many seem not to know that "the state" or "government" separated from the halo of idealism and patriotism, disillusions itself into a mere ruling political set. We must show the people that the happy and successful treatment of disease and misery is personal and individual; that it cannot be done happily en masse, like the turning out of Ford cars; that any clinic system or state system breeds quantity and not quality; that such systems will not change human nature, either in doctor or patient; that such system has failed where tried; that in Austria the system broke down early and left the doctors as mere hangers-on and the people without service; that in England the doctors now carry it on only through patriotism and devotion during the period of reconstruction.

We must not only educate the layman, but overcome the layman's educating the profession, for we must not forget, as Mr. Pritchett relates, that as a matter of fact the practice of medicine, the profession of medicine, since historic time, has been affected almost as much by the layman as by the profession. This as I think, and as I think Dean Emerson in his most interesting and instructive articles on the history of medicine has shown, is extremely dangerous. Further with Mr. Pritchett, the layman cannot distinguish between medicine as science and as an art of healing. He fails to understand the development of medical education along the lines of highly scientific training. He does not conceive medicine as we do, nor is he in position to appreciate much other than the obvious and spectacular. Due to his confusion of thought, he suspects as selfish on our part every legal restriction asked for his own protection. He does not understand why all treatment of disease should come under legal restraint rather than being bred upon one's own belief, religious or otherwise. He can't understand why all matters pertaining to health, individual or public, should be under the control of the medical profession. Even in the profession some can't see why all aids to health, as nursing associations, boards of health, societies, and lodges, should so far as they pretend to promote health first, meet with the approval of the medical profession.

It is an honor to be president of any medical society, but it would be a greater honor to be the president who made his society a vital educational force, with a strong committee on civic policy, divided into sub-committees to look into all matters affecting the profession and the health of the individual, such as private laboratories and clinics, advertising doctors, insurance and compensating companies, civic organizations, municipal and state boards of health, medical colleges, hospitals, publicity in the press, to help regulate ethics, to report to the society and through the society to give out such publicity as will help educate the people.

In regard to the education of the profession, the undergraduate medical school can improve upon the art of teaching, the choice of text books, and the relation and correlation of studies. They can separate postgraduate and undergraduate teaching, cut out the fraud in research work and postgraduate work, cease taking the time of the interne or student in research before he is half qualified in diagnosis, that is, if he intends to practice medicine. College officials and A. M. A. standardized patternmakers should remember that the primary and

fundamental duty of the medical college is to train men to practice medicine and that the general practitioner is the backbone of public health.

If colleges do not adjust their curricula, stop working against the doctor they create, they will soon find themselves working against the people who support them. For some reason the medical profession has not learned how the physician can be a physician, a citizen, a teacher, without incurring the ill will of his fellow doctors. If he is to be branded as a solicitor because he tries to educate the public then the medical societies, boards of health and the medical colleges must assume the position of chief instructors to the community in all things pertaining to health. But the medical colleges cannot wholesomely perform this function, nor the medical profession well tolerate, so long as the college teacher is paid to educate and at the same time be permitted to compete in practice. His advertisement gained at community expense gives him an unfair advantage over the practitioner who is handicapped by professional ethics. Regardless of arguments to the contrary, in a broad sense, as a matter of continued policy and not in a selfish or political sense, I believe such policy unwise and undesirable. Men should take a part of their pay in the honor of their position, and trust, if they so desire, to increased earnings for having held high places of honor and ability. The medical profession should not subscribe to state boards socializing any part of medicine under the plea of education and public health. Boards of health should strive not to force the expense of private health upon the state under the guise of public health. Their supervision of private health and practice will stop progress in medical treatment.

I do not know who was the originator of the idea of state medicine, whether it came from within or without. But I do know there are individuals within and without the profession who are striving openly and covertly to force it upon the people. The president of the National Nurses' Association, in reply to the professional criticisms of Dr. Mayo, rushed to the lay press. John A. Lapp, editor of *Modern Medicine*, went from Chicago to Albany to aid state medicine. Michael Davis of Cleveland and others are fighting for free health clinics and centers. Different individuals and organizations are solving the problem to suit their own desires. We see they offer us nothing. We see we cannot fully trust medical colleges, health boards, insurance societies, U. S. P. H. activities, Red Cross maneuvers, Rockefeller, Carnegie, or any other rich man's foundation, industrial or political organizations, in fact, we have seen we can trust no one but ourselves, and it seems sometimes there is some kind of worm gnawing in our own hearts. We know we have the problem of the pauper, we know the increased cost has made it hard for the middle class, and by way of compliment let me say the reason there is a good solid middle class is because it has been most let alone.

We sympathize with uplifters and reformers, at heart unselfish, but they have become so well paid we mostly distrust. We distrust if we see the monkey in the woodpile and if we do not see him we say he is there just the same. We sympathize with the agents of the Federal Government in a desire to promote the health of the country but not in Federal supervision as in the Shephard-Towner bill. Nor do I believe in the ultimate efficiency of federal bureaucracies supervising state activities under the guise of federal aid or for any state or municipal bureaucracy to supervise the practitioner. Such attempts are un-American, attempts to change our government, and exceed the limitations upon the federal power fixed by the constitution. The Shephard-Towner bill in my opinion would be declared unconstitutional were it decided according to the constitution instead of political sentiment.

We may have to strike at the cost of medicine to the people but not where the lowering of cost will reduce the impetus to scientific medicine. The cost of hospitalization, accessories in diagnosis and treatment can be reduced. The demand for the nurse is as different as the demand for the practitioner and specialist. If every nurse is a $40.00 nurse and every doctor a $25.00 doctor then the cost is too much for many and we ourselves are opening parking places for state medicine. We must find some way whereby the private practice will be more enticing than a federal clinic. We have seen how young graduates went out over the country to various clinics as specialists when in many instances the only qualification as specialists they had was the holding of a federal job in a special clinic organized by bureaucrats. Perhaps we must have more thought for the young men of the profession. Besides adding fuel to the fire of state medicine it does not show a magnanimous spirit to pull the ladder up behind us or to kick out the rounds by which we climb. We must get to the taxpayer in the right light. Right now would be a good time for the farmers to know what state medicine means. Soon as they learn they will find a better way than free treatment and free bed and board for the immoralities of men and women. When they know the medical bureaucratic system in England—and which everybody hates—cost the country $100,000,000 a year and is increasing and will cost us ten times more, they will help us find a way out.

The cry from the masses of people for state medicine comes from the interested group in

each county. The real mass know not what is going on.

But the pauper must be cared for, nor will industrial development be hindered by a procrastinating medical profession. We must come out from behind our intrenchments of the past, realizing that a demand for new relations between the public and doctor is being made, that we cannot sulk in our tents and expect outsiders to settle this demand perfectly satisfactorily to us, that we must take our share in the responsibility, both in the interest of the profession and public, and we can do this only by pointing the way.

We must bear in mind three things—there must be the opportunity for health for every person, protection for everyone against those who do not avail themselves of the opportunity and there must be encouragement for the profession by rewards commensurate with its services. The health problems belong rightfully to the medical profession. This is the portion of man's burden which it must carry. The successful adjustments of such problems and duties as confronts it from time to time will be its answer to society for its stewardship. The medical profession should come together with competent leadership carrying this through the county, state and national societies. But it is time to count heads. We must know where our delegates stand and they must represent the society and not necessarily their own wishes. We must not permit, in the plea for suffering humanity, a bureaucratizing of essential workers. If medicine is not essential it should be abolished, but if it is essential, then it should be as untrammeled as private ownership and have perfect freedom of initiative.

In conclusion, I have tried to show,

1. The elements at work creating the problem,
2. That they have created a problem,
3. What some have done to solve the problem,
4. That no one has considered an untrammeled medical profession in the solution,
5. That it is our problem and unless we wake up, some charmer like Bryan, Hoover, Hayes, will beat us to the answer.
6. That we can solve it through education and organization.

In conclusion, fellow practitioners, I repeat my text—"He that is not with me is against me, and he that gathereth not with me, scattereth abroad."

REMOVAL OF DIPHTHERITIC EXUDATE FROM LARYNX

In taking cultures directly from the larynx, Charles A. Thomson, New York (*Journal A. M. A.*, April 22, 1922), states he has frequently noted that the dyspnea was caused either by loose membrane, which was drawn into the lumen of the larynx by inspiration, thus occluding it, or by a thick mucopurulent material which the patient seemed unable to cough up. In only a small number of cases was the dyspnea due to the attached membrane alone or to an inflammatory stenosis. It was further noticed that this loose membrane came away frequently on the swab; the coughing that followed the withdrawal of the swab frequently expelled the mucus, with the result that the child, who was sometimes ready for intubation, received immediate marked relief; this relief lasted in some cases for from six to ten hours. This observation led to devising means whereby this obstructive material, which tends to recollect after a number of hours, could be removed more thoroughly, thus saving many patients from intubation. A specially devised applicator is used under direct laryngoscopy. It is passed into the larynx just below the cords, and immediately withdrawn. The withdrawal of the swab acts somewhat like the plunger in a syringe, bringing with it a large amount of the mucus and frequently good sized pieces of loose membrane. The result of this procedure was surprising in many cases; patients that were cyanotic and perspiring received as much relief as from intubation—relief that lasted from eight to ten hours, and in some cases was permanent. During this period the child could take nourishment easily, had several hours' uninterrupted sleep and, as a result, his general condition remained much better than if intubation had been done. Usually the applicator treatment had to be repeated two or three times and, in two cases, four times. In no case has pneumonia developed as a result of the treatment, nor did any accident occur from pushing the membrane down the trachea. It was noted, further, that aphonia disappeared earlier in these patients than in those in whose cases intubation was performed. Only those patients were treated who would otherwise have required intubation.

DESENSITIZATION OF HAY-FEVER PATIENTS BY SPECIFIC LOCAL APPLICATIONS

GEORGE M. MACKENZIE, New York (*Journal A. M. A.*, March 18, 1922), claims that the reactivity of the nasal mucosa of hay-fever patients may be markedly diminished by spraying the nose and throat with the specific pollen antigen. In a series of patients given specific prophylactic treatment by this method, the results compared favorably with those in a series of patients treated by specific subcutaneous injections, but were less satisfactory than when a combination of the two methods was employed.

PROTEIN THERAPY

"Resistance" to infection, in its implication of biological reaction to bacterial invasion, has long been considered a strictly specific phenomenon. Theory and laboratory experimentation were largely responsible for this point of view. Only recently Wright has admitted that clinical results have at last forced him to conclude that "inoculation produces in addition to 'direct' also 'collateral' immunization".

William F. Peterson in his "Protein Therapy and Non-Specific Resistance", recently published, says: "It was the clinic that forced upon our attention certain therapeutic results which could not be ignored." With these results we must grudgingly admit we are all more or less familiar—grudgingly because of our antagonism to the introduction of phylacogens, "shotgun vaccines", on what we considered empiric grounds, and to stock vaccines because we believed that the process of immunization varied with different strains of the same bacteria as well as with different species of bacteria. For several years, however, both the laboratory and the clinic have been producing evidence tending to show the marked similarity of all biological reactions to parenteral proteins.

Renaud in 1911 showed that typhoid vaccine had a beneficial therapeutic effect upon a number of non-typhoidal inflammatory processes; Kraus that colon vaccine had practically the same result as typhoid vaccine in the treatment of typhoid. Ichikawa treated paratyphoid successfully with typhoid vaccine and Kraus reported favorable results in puerperal infection treated with colon vaccine as long as ten years ago. From these beginnings the evidence has rapidly accumulated until the use of stock vaccines is commonly accepted, the treatment of arthritis by intravenous typhoid vaccine universally recognized, and the injection of various foreign protein substances such as milk, casein, seralbumin in the treatment of inflammatory conditions admitted as theoretically and practically sound.

Nor is this illogical if, as Peterson points out, "we keep the focus of our attention on the reaction of the body to injury—on inflammation —we find that this reaction, no matter how produced—be it bacterial invasion, intoxication or trauma—is fundamentally similar under all circumstances". In all such processes, however, they may vary in the type of cellular reaction, the amount and composition of the exudate, we are dealing with an effort "to dilute the noxious agent, to remove it by intracellular or extracellular digestion, to neutralize it or to wall it off".

From a therapeutic standpoint but two avenues of approach are open in the presence of a cause of inflammatory reaction. We can attempt to destroy the causative agent by introducing an antitoxin, antibacterial agent or chemical; or we may confine our efforts to altering the inflammatory reaction of the body itself. The latter explains the reason for non-specific protein therapy—it is a therapeusis whereby we alter the reaction of the organism to the etiologic agent by promoting or retarding autolysis by hastening resorption and the reparative processes—and as such its *raison d' etre* can fairly be said to have been established beyond question.

PREVENTION AGAINST DIPHTHERIA

Medical men have not attached sufficient importance to the subject of the control and prevention of diphtheria. All have known of the inestimable value conferred upon humanity by the discovery and use of antitoxin, which has so greatly reduced the mortality, but few seem to appreciate the newer development in diphtheria control brought about by the discovery of the wonderful protective effect of toxin-antitoxin. Heretofore we have been content to give small immunizing doses of antitoxin to children who have been exposed to diphtheria, but such injections only protect the children for about three weeks. On the other hand, toxin-antitoxin protection lasts for years and probably for life. This result is secured in much the same manner that protection by antitoxin is secured, namely, by the injection of small doses of sterile serum into the arm once a week for three weeks. It is claimed that this makes the child as safe from diphtheria as vaccination does from smallpox, and it is asserted by prominent clinicians and public health officers that if every child between six months and five years of age could have this treatment, diphtheria eventually could be wiped out. Until this protective treatment is rather universally used, diphtheria will continue to prevail in various communities with a varying death rate, depending upon the promptness and certainty with which antitoxin is administered. The safety and effectiveness of this protective measure has been established beyond the question of a doubt, and it only remains for the public to become conversant with the facts. The dissemination of the knowledge must come through not only the activity of

health boards but the personal influence of family physicians who come in direct contact with people. The results to be secured are certainly worth while.

DEATH OF DR. EDWIN WALKER

In the death of Dr. Edwin Walker, at his home in Evansville, on April 23, 1922, not only does Evansville, but Indiana and in fact the Middle West, lose one of its most capable surgeons and enterprising citizens, beloved by all who came in contact with him. Dr. Walker had the distinction of being an indefatigable worker, with a mind centered upon scientific achievement and the good that can be done to humanity, and of lofty ideals in his intercourse with his fellow men. He was honored by the American Medical Association in serving as its vice-president. He served as president of the Mississippi Valley Medical Association, and his own State Association honored him many years ago with the presidency. He was at all times devoted to the best interests of the medical profession, and his loyalty to his friends was especially noteworthy. He not only has perpetuated his life's work through the establishment of a hospital which bears his name, but his achievements in the interest of scientific medical progress and in allaying the sufferings of humanity have left an imprint that will long survive.

INDIANA UNIVERSITY SCHOOL OF MEDICINE SUMMER COURSES

Postgraduate courses will be offered during the coming summer by the Indiana University School of Medicine, Indianapolis, during the six weeks' period, June 8th to July 20th, 1922.

Courses will be offered by the Departments of Pathology, Pharmacology, Medicine, Surgery, Gynecology, Genito-Urinary, Rhinology, Otology and Laryngology, Ophthalmology, and Dermatology and Syphilology.

The Department of Medicine will offer a course in internal medicine which will consist of ward rounds at the Robert W. Long Hospital, including methods of medical laboratory diagnosis necessary for the study of patients on the wards.

Clinical work in surgical diagnosis will be offered; also work in surgical pathology. In the former case, whenever indicated at operation, the opportunity will be given to prove or disprove the diagnosis. In the work in surgical pathology, special stress will be laid upon gross pathology and upon the relation of the pathological condition to the clinical picture. Also the prognosis as determined by the pathological diagnosis will be discussed.

A course in biochemistry on some of the more recent chemical methods includes the analysis of the blood, determination of acidosis, detection of diabetes and hyperthyroidism by the determination of the sugar tolerance and the basal metabolism will be given. The work will consist of lectures and practical laboratory work.

The Department of Pathology and Bacteriology will offer courses in pathology and disease production and resistance.

The course in pathology will cover pathological changes in general, and those changes characteristic of the more common diseases, including various infectious diseases, cardiac, arterial, renal and glandular diseases, anemias, leukemias, neoplasms, etc. The course will occupy six weeks, with five lectures per week followed by laboratory periods. Study will be made of the gross and microscopic features of pathological material illustrative of the changes discussed. The projectoscope will be used for demonstrating microscopic changes in the sections to be studied. Those enrolled in this course may attend all autopsy examinations made by the officers of this department during this period.

The course in disease production and resistance occupies six weeks with three lectures and three laboratory periods per week, and will summarize the present understanding of the mechanism by which various disease manifestations are produced, and the reaction of the body to the various forms of injury. The major portions of the discussions will relate to diseases of bacterial origin, but the pathological physiology of toxemias, mechanical injuries, burns, neoplasms, and diverse other disease processes will be presented. Stress will be laid on the reaction of the body to the various forms of injury, and the relation of this reaction to the course of the disease and to symptomatology. The principles of immunity and the application of the various serological tests and other immune reactions to diagnosis will be presented together with the relation of serum and vaccine therapy to the mechanism of the body's resistance.

The courses to be offered in gynecology, genito-urinary diseases, rhinology, otology and laryngology, ophthalmology and dermatology and syphilology will consist of two two-hour periods per week. Both hospital and dispensary clinical material will be available for these courses.

For the benefit of physicians who are able to give full time to the work, an effort will be made to arrange the schedule so as to permit the taking of as many courses as possible.

Since the number of students enrolling in these courses must necessarily be limited, and also that the giving of the various courses is dependent upon the number of applicants for each course, it is urged that those desiring to take the courses apply at once to the Registrar,

Indiana University School of Medicine, Indianapolis, for registration card, indicating the courses desired.

For further information address Registrar, Indiana University School of Medicine, Indianapolis.

DISCRIMINATION AGAINST AMERICAN PHYSICIANS IN VIENNA

If anyone believes that the Germans are not treasuring a grudge against Americans, all he has to do is to read the statement issued by the officers of the American Medical Association at Vienna to American physicians who are thinking of taking postgraduate work in Vienna. This statement, which is duly signed by the officers, is as follows:

VIENNA, March 24, 1922.

TO AMERICAN PHYSICIANS:

The American Medical Association of Vienna was established 1904.

The objects of the Society are to promote the social intercourse and the scientific advancement of its members, to provide information in regard to the scope and relative value of courses, and to furnish data for the rapid orientation of new members in regard to pensions, rooms, restaurants, etc. (Article II. of the Association's Constitution).

It also regulated, in agreement with the teachers, the different fees charged for post-graduate work, and arranged all the courses taken by American doctors. It worked to the satisfaction of both the American doctors who came to Vienna for post-graduate study as well as for the teachers of the Vienna University. A great many courses were placed under the control of the A. M. A. of Vienna, as far as their personnel, number of members, and hours were concerned. These were called bookcourses and were given for a fee approved of by the Society. The so-called "Blue Book" comprised all these courses and explained how they were conducted. The Blue Book was issued every year on January 1st, and the members of the A. M. A. of Vienna as well as the teachers abided by its rules. It was not only the quality of the teachers but also the propaganda which the members of the A. M. A. carried on in the States that made Vienna the hospitable home of 300—400 American doctors every year. Things ran smoothly most of the time up to 1914 when the war broke out. During the war, Dr. J. Lange, a former president of the A. M. A. of Vienna, remained in Vienna and had the misfortune of breaking down physically as well as financially. The lecturers in recognition of his services and probably also in expectation of Dr. Lange's sending back 150 American physicians to Vienna, as he promised, made up a purse with which to send him home to Chicago. They also defrayed the expenses of a Blue Book, which he had compiled without any authority whatever from the A. M. A., and in which he printed exorbitant fees for the courses to be given by the various lecturers. This is the Blue Book of 1919.

These preliminary remarks, we find necessary for the full understanding of our present unfortunate difficulties with the Vienna Faculty concerning fees charged for courses.

In the summer of 1921 about 12 American physicians came to Vienna to take courses, and first began to complain about the fees they were asked to pay. They were charged all the way from one to ten dollars for one hour.

The discrimination which was going on against American physicians became unbearable, for it was a twofold discrimination. To understand this, you must know that two sorts of courses were being given at the clinics.

1. Courses read in German and accessible to doctors from any part of the world. For these courses, the lecturers charged the Austrian physicians about one-fifth of what they charged physicians coming from the newly formed republics of dismembered Austria. Such physicians were called (Neu-Auslander) "new" foreigners. Doctors, however, who came from countries like France, Switzerland, Holland, England, etc., were called (Alt-Auslander) "old time" foreigners, and they were charged ten times as much as the Austrian physicians who happened to take the same course.

Our men, as long as they were not asked to pay more than the so-called "old" foreigners, never refused to pay ten times more than the Austrian doctors. But they did refuse to pay more than the "old" foreigners (Swiss, Dutch, Italian, French, etc.). They could not understand why they should be considered better off financially than the Swiss or Dutch for instance because the franc and Dutch guldin increased in value in the same ratio as the dollar.

2. The other possibility open for the American doctors to take courses was for them to club together, but since there were often only a few Americans present such courses would seldom comprise more than two to four members. When the teachers were engaged, the Americans were charged three, four, five or even twelve dollars per hour, regardless of whether the course was given in German or English. That means the teacher got for his working hour, if he happened to work for American doctors, three to twelve dollars, which in Austrian crowns in August, 1921, amounted to 3000—12000 crowns. This same teacher, teaching the very same subject, would sell his hour, according to the printed official program for post-graduate work issued by the Vienna Medical Faculty, for 2500 crowns to any other foreigner, and 250 crowns, at the most, to an Austrian. It was, therefore, evident that, no matter whether the American physicians took courses jointly with physicians of other nations or had them arranged for themselves only, they were unjustly discriminated against.

Under such conditions it was but natural that the former American Medical Association was reorganized, and a president elected who, owing to his Vienna origin, was thought to be capable of adjusting the matter. The president had a committee work with him and after August 28th many joint meetings were held with the representatives of the teaching body of the University. In these meetings, the unjustified and unfair attitude displayed toward the American physicians was thoroughly discussed. The committee brought detailed charges of conspicuous discrimination against American doctors. On Nov. 19th the American physicians offered a maximum fee of three dollars for the teacher's hour, proving absolutely that three dollars was 4 to 10 times more than any other foreigner was asked to pay for the same course by the same teacher. The committee also proved, in a detailed memorandum submitted to the teaching body Nov. 19th, 1921, that three dollars per hour in Vienna was a great deal more than ten dollars paid to the best teacher in post-graduate work in New York. It was proved that the Viennese teacher could buy more for three dollars in Vienna than the American teacher could for ten dollars in New York. It was further shown that, if the terms as proposed by the A. M. A. of Vienna were accepted by the medical teaching staff, many more

American doctors would be induced to come to Vienna for post-graduate work, and would thereby re-establish the highly satisfactory pre-war organization.

After prolonged debate and negotiations the terms were acceptable to all departments with the exception of eye, ear, and skin (Clinics Meller, Neumann, Dimmer, Finger, Riehl). Without the cooperation of these clinics, however, a satisfactory organization would be impossible, for 75 percent of the American doctors are directly concerned with these departments.

Since our many attempts to reconcile the relationship between the docents and the A. M. A. of Vienna have been unsuccessful in procuring a definite agreement, we feel it our duty to let medical men in the United States know what sort of discrimination is taking place against American physicians.

We have requested the U. S. A. Legation in Vienna to intercede and endeavor to change this lamentable state of affairs, but we have little hope of any success in this matter.

P. S.:—We shall ask the *Journal of the A. M. A.* in America to print this statement to correct the impression conveyed in the letter written by Dr. G. H. Kress of Los Angeles, Cal., which appeared in its Correspondence Column Dec. 31th, 1921. Dr. Kress on leaving Vienna was in full knowledge of the condition described above—in fact he was the author of the memorandum presented to the teaching body of the University of Vienna on Nov. 19th, 1921, enumerating all the facts given above—but we surmise that Dr. Kress on leaving Vienna had hoped that the teaching body of the University of Vienna would surely not turn a deaf ear to the just complaints of the American physicians.

A FEW ILLUSTRATIONS OF DISCRIMINATION

In the official program of the Viennese Medical Faculty for post-graduate courses to be given October, November and December, 1921:

Docent Elias announces a course for metabolic disorders; fee 500 crowns per hour of his time (if taken by Austrians); the same course he offered to the A. M. A. for five dollars per hour, or according to the exchange value of the dollar at that time 40,000 crowns per hour!

Docent Stein announces a course for skin diseases and cosmetics; fee 400 K per hour of his time (if taken by Austrians); the same course he offered the A. M. A. for five dollars per hour = 40,000 K per hour from Americans!

Docent Denk announces: "Selected Chapters from Special Surgery" for 250 K per hour of his time (if taken by Austrians); from the A. M. A. he asks five dollars per hour of his time = 40,000 K!

In January and February, 1922, when the dollar went up to 9—10,000 K in exchange:

Docent Hirsch asked in his course, "Anatomy and Pathology of Nose and Sinuses," from old foreigners 6000 K for one hour of his teaching time, from Americans four dollars = 36—40,000 K.

Prof. Kyrle, in a skin course given in February to 2 Swiss, 1 Egyptian and 3 Americans, asked 30,000 K from the Swiss and Egyptian and 60,000 K from the Americans—and they paid it!

Sincerely,

P. S. GRAVEN,
W. G. SAHR,
F. F. SCHMIDT,
JOHN PENNINGTON,
T. L. BLANCHARD.

DETROIT APPEARANCE OF LORENZ, WEDL & CO.

Now that the curtain is about to go down on the Lorenz vaudeville show in Detroit, the blessings bestowed on our cripples by our distinguished Austrian visitor may be appraised with some regard for the actual facts, and with some hope of enlisting popular interest therein.

Dr. Lorenz has not performed a single operation, public or private, that could not be as well done by five of Detroit's orthopedic surgeons. In the course of the day's work these Detroiters do everything that Lorenz can do.

Dr. Lorenz's widely advertised Lolita Armour case in Chicago involved precisely the same operation that had previously been performed by a Detroit surgeon who is still in practice.

Dr. Lorenz's reputation for his treatment of congenital hip trouble, as first revealed by an Italian doctor, was well deserved in its day; but there are men in Detroit, and all over America, who are quite as adept in administering the same treatment now. Chicago surgeons report that of 26 dislocated hips operated on by Dr. Lorenz on his last visit to America, only two had been successfully reduced.

Dr. Lorenz limited his free clinics in Detroit to the simpler cases, including those that appear spectacular, thus reserving more difficult cases for private inspection, provided the patient was able to pay his fee.

Dr. Lorenz collected $100 in advance from every private patient he saw in New York, whether he could do anything for the patient or not. He told a New York newspaper that his "receipts of a single day were never as much as $3,000". His Detroit fee for private patients has been reported at $50 and upward, according to the patient's purse.

Dr. Lorenz's operations depend for their success, as do all such operations, not on the skill of the operator alone, but on subsequent treatment, which must continue for two years on the average in orthopedic cases. Some of our own orthopedic surgeons refuse to operate on patients outside their own city rather than risk the failure of subsequent treatment.

Dr. Lorenz has not done anything for charity in the treatment of Detroit's cripples that is not done every week by Detroit's orthopedic surgeons, and every year by other orthopedic specialists whom they bring here for open clinics.

Dr. Lorenz was brought to America by Anton Wedl, a New York lace importer, and another New York business man whom Mr. Wedl does not name. Dr. Lorenz says he came to repay Austria's debt for America's care of Austrian children. Wedl handles all the money Dr. Lorenz collects.

If that money goes to the relief of Austrian children, as has been assumed by some, Dr.

Lorenz and his financiers are not repaying their debt to America, but increasing their obligations.

If it goes into the pockets of Lorenz, Wedl & Co., America will occupy a high place on the sucker list of a professional gentleman engaged in feathering his own nest in the name of philanthropy. That may possibly explain why Dr. Lorenz and his colleagues neglected so many American prisoners in Austrian camps and turned them out with deformities instead of sound limbs.

At any rate, taking up a collection has proved to be an essential part of the Lorenz program in Detroit and elsewhere. He does not even stop at attaching his name to an advertisement for corsets.

Scientifically speaking, the difference between Dr. Lorenz and our own orthopedics is a difference in stage effects dramatically and freely furnished our distinguished Austrian visitor by susceptible newspapers.—Editorial *Detroit Saturday Night. Journal Michigan State Medical Society.*

LESSONS FROM LORENZ

Before Dr. Lorenz visited Detroit, prominent medical men throughout Michigan were seeking some means of securing legitimate publicity on medical affairs without violating the ethics of their profession. Their problem was to offset the commercial advertising of the quacks by carrying medical truth to the public without commercializing their profession by buying advertising themselves.

The need of the medical profession for legitimate publicity, and the value of it to the public, were impressively demonstrated by the results of the free publicity accorded Dr. Lorenz in American newspapers. Many intelligent people had never heard of the possibilities in orthopedic surgery until Dr. Lorenz appropriated a large percentage of the newspaper headlines. Comparatively few people knew that there were orthopedic surgeons in Detroit and other American cities quite as skillful as Dr. Lorenz, or that these surgeons were doing their full share of free clinical work.

Popular interest in Dr. Lorenz has a broad educational value, and will continue to have during the months that his patients must rely on local practitioners for treatment. Dr. Lorenz himself recognizes "amazing skill among physicians" in Detroit. Dr. Kidner of Receiving Hospital announces after x-ray examination that Dr. Lorenz did not effect a complete cure in any of his operations at that institution, and a more notable fact is that the cases Dr. Lorenz selected for operation were among the simplest. Nevertheless, the staging of the Lorenz operations in such a dramatic way as the newspapers have done it has produced a sort of revival in orthopedic surgery in Detroit and elsewhere.

Yet Dr. Lorenz's specialty involves only one branch of medical practice. There are many others that the public knows as little about. How many people realize, for instance, that it is a common thing for our oculists to straighten cross-eyes? Publicity will tell them; and the kind of publicity devised by the Michigan medical organizations and the University of Michigan for dissemination through the lecture platform and the News Radio Station will be welcomed by unfortunate people in search of health and strength. And it ought to be an effective answer to quackery.—Editorial *Detroit Saturday Night. Journal of the Michigan State Medical Society.*

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

To use a slang phrase, doctors are overlooking some good bets when they fail to read the advertising in medical journals, and we especially call attention to our own advertising pages where announcements of interest to many members of the medical profession will be found. Not infrequently some rather rare bargains in supplies are advertised.

GOVERNMENT reports continue to extol the virtues of carbon tetrachloride as an effective agent in the treatment of hookworm in human beings. It was first used as an efficient remedy for hookworm and related blood sucking worms in animals, and it is only within the last few months that it has been found to be equally efficient in the treatment of hookworm in the human. Fortunately the treatment is unattended with danger, and it is extremely cheap, the chemical being one that is commonly used for cleaning clothing.

IT may be of some interest to the readers of this Journal, especially those interested in

radium, to know that recently Dr. Albert M. Cole and Dr. Raymond C. Beeler have lost, through theft, fifty-five milligrams of radium. This was contained in four needles and one five milligram plaque. The radium was taken from a combination safe, the thief working the combination successfully. Fifty milligrams in two tubes in an applicator was overlooked by the thief, probably establishing his ignorance of radium. It is possible that this thief with a radium burn may come under the notice of some physician with this information in mind.

THAT microbes harbored by rats can induce jaundice in human beings was convincingly demonstrated for the first time recently when a young woman bacteriologist in the State Health Department Laboratories at Albany, New York, became infected by accidentally pricking her finger with the needle of a syringe containing a virulent culture of the leptospira from a rat which had been prepared for the inoculation of a rabbit. Now that it has been definitely proven that rats harbor a germ which will infect human beings, an immediate and relentless war on these rodents should be instituted.

A FORT WAYNE woman has sued a shoe store for five thousand dollars damages because a pair of shoes which she purchased of them had paper heels which suddenly gave way while she was wearing the shoes and precipitated her to the ground with more or less serious injury. So far as we know this is the first case of the kind on record, and while it probably will fail in its purpose, yet it shows the length to which people will go in an attempt to secure something unfairly, though it may be that the matter has been stirred up by a shyster lawyer. It really reminds us of some of the suits for malpractice sometimes brought against physicians without justifiable cause.

RADIUM owners will be interested in a new radium insurance policy which has recently been offered for sale by the Insurance Company of North America. Lloyds of London, who previously handled the major part of the radium insurance, recently raised the annual premium rate to 5 percent. This action met with universal disapproval, and a number of interested Philadelphia physicians set about to secure a radium policy that would give owners protection under all reasonable conditions. The result is this new policy offered by the above mentioned firm, which covers all risk, at a premium of 2 percent per year, but with the payment of but 75 percent of the loss instead of 100 percent.

IN an address delivered before the meeting of the secretaries of state medical associations, Dr. Alexander R. Craig, secretary of the American Medical Association, made a very important suggestion when he said "the council of the State Medical Association should not only serve as a court, but it should also be in fact the active agent for guiding the organization within the State. The councilors personally should visit, correspond with, and through other means supervise and stimulate the activities of the county medical societies". To do this work effectively will entail considerable thought and effort, but if the best results are to be obtained the councilors must be diligent and active in the performance of the duties of their offices.

THE chiropractors and all other pseudo-medical cults are opposing all forms of legislation that have the remotest effect upon the legitimate practice of medicine. They give their support only to such legislation as throws open the doors for all kinds of chicanery and quackery in the practice of the healing art. With true consistency they are opposing Senate Bill No. 2764, introduced by Senator Watson of Indiana, which provides for the transferring of some of the medical officers in the reserve corps to the regular Public Health Service and thus makes for more efficient service through the increase in the number of permanent officers. We shall be interested in knowing just how great the influence of the pseudo-medical cults will be in defeating this very wise bill.

THAT Indiana is waking up to the dangers of some of the medical uplift schemes proposed by erstwhile reformers is evidenced by the fact that the Indianapolis Medical Society, the largest local medical society in the state, has adopted a set of resolutions covering opposition to various forms of medical practice which are paternalistic in character or tend toward State Medicine. The resolutions are published under Society Proceedings in this number of THE JOURNAL and are worth reading by every medical man in Indiana. We hope that this step by the most prominent local medical society in Indiana will result not only in serious consideration of some of the evils that confront us, but actual opposition to those enterprises that have as their ultimate end competition with private practitioners and finally the practical abolition of the private practice of medicine.

Now that protection against diphtheria for years and perhaps for life can be obtained by the injection of toxin-antitoxin, much as we protect against smallpox by vaccination, we wonder if the Anti-Vaccination Society will not add to their propaganda a fight against the

newer protective measure. Just why there should be such strenuous opposition to tried and tested methods of preventing such terrible diseases as diphtheria and smallpox is hard to understand. Even by the wildest stretch of imagination the effects of the remedy are less than the effects of the disease, and, except in very rare instances and those usually due to faulty technic or to some coincident cause, no ill effects have been produced by these protective measures. Therefore, opposition to them must be a question of bias based upon ignorance, or, perhaps we might say, pure obstinacy for the joy that is in it.

TYPHOID fever in Indiana has been steadily reduced from 21.2 percent in 1916 to 9.7 percent in 1920 per one hundred thousand population. However, this rate is altogether too high, and there is no reason why it should not be reduced to meet Massachusetts and Wisconsin, which have the lowest typhoid death rate. The amount of typhoid fever in the community is recognized as one of the indexes of its healthfulness, and it also indicates the condition of sanitation. There is no reason why Indiana should be behind a large number of populous states like California, Connecticut, Illinois, Michigan, Massachusetts, Minnesota, New Jersey, Ohio, Wisconsin and a few others which apparently pay more attention to sanitation than we do. This is a subject worthy of the attention of our State Board of Health, with the suggestion that more attention be given to the enforcing of sanitary regulations with special references to health officers in small towns and rural communities.

DOCTORS are interested in good roads and they should use their influence in helping our road commissioners in securing federal and state appropriations from funds now available. We call attention to this matter for the reason that it was reported that in some districts in Indiana it would be possible to build roads without a cent of expense to the people in the vicinity in view of the federal and state funds that are available for the purpose, and yet the residents of these communities are showing absolutely no interest in the matter. In one or two instances the State Highway Commission has even pointed out to some of the prominent residents of certain districts where good roads are needed that an effort should be made to obtain roads that could be secured with little or no local expense. Certainly the doctors who are using roads constantly ought to take some interest in the matter. One of the ways in which this can be done is by joining the Hoosier Motor Club.

THE Harmer Laboratories Company has been scattering broadcast to the medical profession of Indiana literature on Mon-Arsone, "a new and non-toxic arsenical for the treatment of syphilis". The literature states further that with this drug "the toxic, corrosive and uncertain reactions attending the use of arsphenamine have been entirely eliminated" and that "it has a therapeutic value equal to arsphenamine, but extensive case reports fail to record the slightest toxic reaction following its use". Extensive experimental work carried on under the direction of the Council on Pharmacy and Chemistry of the American Medical Association has brought forth the report that the claim that Mon-Arsone has a therapeutic value equal to that of arsphenamine is premature and unwarranted; that Mon-Arsone should not be used except under conditions that justify the experimental trial of an unproved drug; and that the advertising propaganda for the drug by the Harmer Laboratories Company is to be deprecated.

THE high cost of publication is driving many medical journals out of existence either through complete suspension or amalgamation with other journals. Even the old independent medical weeklies are disappearing, and the last of them, the *New York Medical Record,* has been combined with the *New York Medical Journal,* which appears semimonthly. On the other hand, the greatest medical periodical of them all, the *Journal of the American Medical Association,* continues as a weekly and constantly grows in importance, not only from the fact that it goes to such a large number of readers through membership in the A. M. A., but because of its high ethical and scientific standards. It also is true that the State Journals for the most part are growing in popularity and importance, for with few exceptions they are run on a high ethical plane and aim to represent the interests of and to be of real practical value to the readers. There is no longer any room for the purely commercial medical journal and we are thankful that they are passing out of existence.

THE country seems to have gone crazy over results secured from radio phones, and receiving sets are being put into commercial houses and private homes with a rapidity that taxes the manufacturers. The more powerful receiving sets, when properly installed, permit an audience of several people to sit in a room and hear lectures or concerts at sending stations a thousand or more miles away. At present the expense of producing these programs is an advertising venture for various concerns, and eventually when the novelty wears off or through lack of appropriate return on the investment,

these programs will not be given as they are now, subject to the enjoyment of any and all who own receiving sets and without expense. While the present craze lasts there is a wonderful opportunity to educate a large portion of the public in public health matters and we are glad that the New York State Department of Health is taking advantage of the opportunity by giving short public health talks. These talks should be not only pertinent but short and to the point. They should be of practical value in giving information to the public which will aid in the prevention of disease and the preservation of health.

OFFICERS of our county as well as state medical association should set a good example so far as the ethics of the profession are concerned. That their actions are not above criticism is evidenced by numerous newspaper clippings received at this office from various parts of the state which give glowing accounts of operations or other professional attention rendered patients by this or that doctor—full names being given. Usually such newspaper clippings are sent in with such notations as "and this man is the president"—or secretary, as the case may be—"of our county medical society". As we have stated more than once, whenever you repeatedly see a doctor's name in one of his home papers in connection with some wonderful operation or other startling professional services rendered, you can make up your mind that that doctor has courted the publicity given if he has not actually asked for it. Any reporter or editor will respect the wishes of any doctor who requests that his name be omitted in connection with newspaper publicity, and there is absolutely no excuse for repeated violation of this phase of medical ethics.

IF Secretary Combs had any doubt about the county secretaries reading the membership statistics in THE JOURNAL, it was dispelled when a letter was received from Dr. Dugdale, secretary of the St. Joseph County Medical Society. In the April number of THE JOURNAL a list was published of the largest county societies in the state, and, through the State Secretary's error, St. Joseph County was not listed in its rightful position. However, during the month of April, since that report was published, St. Joseph County has sent in enough additional memberships to step them up in the column until now they are in third place. In fact, Dr. Dugdale was the first secretary this year to send in the dues of all of last year's members. It is perhaps a commentary on the recent migration of physicians to note that the larger societies, Marion County, Vigo County, St. Joseph County and Vanderburg County, have the largest memberships in the history of their respective organizations. It is the less populous counties that have lost some of the few doctors they used to have, and the presumption is that these doctors have moved to the larger cities.

THE legislative committee of the State Association may well consider the advisability of having a paid representative to look after legislative interests in Indiana as they affect the medical profession. The results of the recent primaries indicate the necessity of doing political work prior to the convening of the legislature. We might just as well face the fact that we must indulge in politics if we are going to get anywhere, and act accordingly. Too long have we depended upon intelligence and consistency in the framing and enactment of laws that directly or indirectly affect medical practice, only to discover that the average legislator is not guided by sense or reason but by political influence, and to get under the skin of that type of legislator means that we must take a hand in molding political influence. We can't do this by pursuing an apathetic course until the legislature convenes and then frantically work to head off iniquitous medical legislation that should have been prevented by earlier and more effective action. We may continue to consider it distasteful to enter into politics, but we are not going to make any real progress or even protect the interests of the medical profession until we do engage in politics, and we might as well begin at this late date. One way to do this is to have paid representatives who at all times will be "on the job".

AGAIN we desire to call the attention of medical men to the propriety of investigating before paying good money for securities of any kind. Our reasons for doing this are two-fold: First, generally speaking, doctors are poor business men, and the most gullible on earth when it comes to making investments; and, second, right at the present time the doctors in Indiana are being solicited to buy stocks and bonds in an enterprise of questionable value, and to further the sale of these securities among members of the medical profession the solicitors are showing letters of endorsement from several physicians of high standing. No matter what the claims of solicitors may be, nor how glowing the prospectus report may show up financial conditions, it is a wise plan to thoroughly investigate any proposition before investing your hard earned money in it. This means the securing of a statement of assets and liabilities, which statement should be analyzed carefully and proven to be satisfactory from an investment standpoint. Any conservative banker or the bond department of any of our well-estab-

lished banks will determine the safety of any contemplated investment, and if doctors more often would take advice from such sources, and not "fall" for the glib talk of a stock salesman or promoter, they would lose less than they do now from bad investments.

THE American Relief Administration in Russia undoubtedly is doing a wonderful work in relieving distress in that misguided and poverty stricken country. The twenty million dollars appropriated by Congress, and still other means that have been contributed by charitable persons in America, have gone a long way toward relieving the famine infected districts and preventing starvation of hundreds of thousands of peasants, and especially peasant children who suffered most. However, one cannot help feeling a little antagonistic to this relief project in view of the fact that many of those who accept our aid will at the first favorable opportunity turn upon us. Perhaps the bolshevistic leaders already are chuckling to themselves because we have, in a measure, aided their cause. Of especial interest to the medical profession has been the work done by the relief administration in equipping the hospitals with new instruments, medical supplies and surgical dressings so badly needed. In addition to this, daily food rations to the hospital patients and to undernourished children are being furnished without stint. A need that was taken care of to the great relief of sufferers was the furnishing of ether and chloroform for anesthesia. Previous to the furnishing of this relief, each person coming to the hospital for an operation was asked to bring his own anesthetic, but this rule availed nothing, as anesthetics were unobtainable or, in rare instances, at prohibitive prices. Therefore, it became necessary to perform minor operations without administering an anesthetic, and even amputations were performed in that manner, not even the sedative influence of opium being at hand. This work is truly a work of charity, and let us hope that the gratitude shown at the present time may be felt for years to come.

A CHIROPRACTOR has written us relative to our criticism concerning the cult and very pertinently remarks: "If it is wrong to practice chiropractic, why are the states continuing to grant charters for the establishment of chiropractic schools and colleges?" He then goes on to say that perhaps we would accomplish more by preventing the chartering of these establishments than by attacking those who are practicing under the charters that have been granted. We admit that there is some truth in the logic, but desire to point out that a charter merely grants permission to do certain things, and does not prevent the enterprise so chartered from doing some things that are in direct violation of laws which have no bearing upon the charters. For instance, a charter may be granted for the teaching of chiropractic, but the actual practice of chiropractic comes under quite another law which prescribes the qualifications of any who practice the healing art. The whole trouble with the chiropractic situation is that the law covering the practice of the healing art is not enforced. We have enough laws but they are not worth the paper they are written on unless enforced. If all of the states in the union had possessed Boards of Medical Examination and Registration with a particle of backbone, and had enforced the existing medical practice acts, we wouldn't hear a word about chiropractors or any other pseudo-medical cults. In the State of Indiana we had an inefficient and spineless Board of Medical Registration and Examination for a great many years. That Board prosecuted and persecuted a lot of graduates of regular medicine because through some technicality or other those medical men were unable to comply with the provisions of the medical practice act. At the same time the Board permitted quacks and members of the pseudo-medical cults to escape, and in consequence we at present have the state overrun with a lot of incompetents who should have been prosecuted for practicing the healing art unless they complied with the laws of the state. Now the number of such offenders is so great that prosecution seems futile, and yet every mother's son of them are law breakers, to say nothing of being incompetents and dangerous to the welfare of the community. The chiropractic teaching is irrational, inconsistent, and based upon the grossest ignorance. Our state laws are for the protection of the people and specify educational requirements that should be exacted of everyone who desires to practice the healing art. The law is eminently fair and makes no discrimination in the schools of medicine when it demands that all shall have the same educational requirements. When it comes to the application of treatment, nothing is offered in objection to any plan of treatment which the licensed practitioner may desire to employ. The law as it exists should be upheld, and the reason it is not upheld is through the laxness of our medical boards, and the apathy of the medical profession in engaging in any sort of legislation which while protecting the public probably would be considered as inaugurated through selfish motives. Probably in time the public will realize the injustice of the whole situation as it pertains to the deification of ignorance, and restrictive legislation will be enforced. In the meantime it is not necessary to attack the charters of chiropractic institutions, for chiropractic schools can, and do, operate without charters.

OUR editorial in the April number of THE JOURNAL concerning the imposition of insurance companies in general, and the Lincoln National Life in particular, upon the medical profession, has brought forth a number of interesting communications. One communication, giving a series of letters which passed between an Indiana physician and the above mentioned insurance company following the presentation of a bill for service rendered in filling out one of their regular questionnaires, is of sufficient interest and importance to merit the attention of medical men in general. We are publishing the correspondence herewith:

FIRST LETTER

Fort Wayne, Indiana, April 10, 1922.

DR. —. —. ————.
————, ————.

Dear Doctor:

We are in receipt of your statement for $———— for furnishing this Company with information on ————, a patient of yours, who has applied to us for insurance.

We have always felt (possibly we are in error) that a physician's professional responsibility toward his patient does not end entirely with the mere completion of the treatment he was to have, but we have felt that the duty still remained with the doctor to impart information regarding this treatment when such information would not have a derogatory effect but would perform a distinct service. For instance, in the case of Miss ————, we would not have been justified in issuing a policy without knowing that there was not a more sinister aspect to the condition for which you treated her than was set forth in her statement and without that information we would have been unable to perform what we are pleased to call a distinct service in giving her protection.

The Mayo Clinic, at Rochester, Minn., Dr. G. W. Crile, of Cleveland, Doctors Thayer and Barker of Johns-Hopkins Hospital, and numerous others are continually filling out our blanks because they believe in insurance and know that they are assisting their former patients who are deserving of protection and are also serving a public welfare institution, which life insurance undoubtedly is.

As this information is always furnished us without charge, it has occurred to us that you do not fully understand, or have not considered, the exact significance of this information.

While the facts which you have given us have been an accommodation to the Company, yet by giving them to us you have more directly favored your patients by assisting them in obtaining the insurance which they desired. Physicians have always been glad to cooperate in this manner, and we believe that after regarding the matter from this point of view, you also will be glad to be numbered among those physicians with whom we have had similar dealings.

LINCOLN NATIONAL LIFE INS. CO.

REPLY

S—— B———, Indiana, April 14, 1922.

GENTLEMEN:

I am in receipt of your letter in reply to my statement for service rendered in the case of Miss ———.

As to a physician's professional responsibility toward his patients—the practice of medicine, like selling life insurance, is a matter of business. This applicant has received value in full for such fees as paid for service I have heretofore rendered, a just fee, commensurate with my knowledge of what it costs me to operate my business, has been charged. Your Company is in business primarily to earn dividends and you base your premium rate on what experience has shown to be adequate to meet losses, pay necessary expenses and earn a return on money invested. Your interest in your applicant ceases after you have paid his, or her, death loss, for you deem such payment consummates your obligation, and also when the applicant chooses to quit paying premiums.

If the service I have rendered you concerning this patient was given for any humanitarian reason it might be granted gratuitously; but it is not, it is to protect your Company's business.

You grant in your communication that the facts in this case as furnished have been an accommodation. I go further and state that they are a distinct business asset and as such are valuable to you or you would not seek such facts and opinions.

Now as to the attitude of various other physicians, it interests me not. Many physicians choose to go out as medical missionaries without hope of reward or compensation.

Your classifying an insurance company as a public welfare institution is a little far-fetched. They are distinctly operated for profit and have no harbor for the deserving poor or destitute.

I, like many other physicians, do a certain amount of business for which I receive no remuneration, some of it we class as charity; but when I render service to those who are able to pay I feel that it is their duty to do so. A statement of fee commensurate with service has been rendered in this particular case.

Very truly yours,

—. —. ————.

INSURANCE COMPANY'S REPLY

Fort Wayne, Indiana.

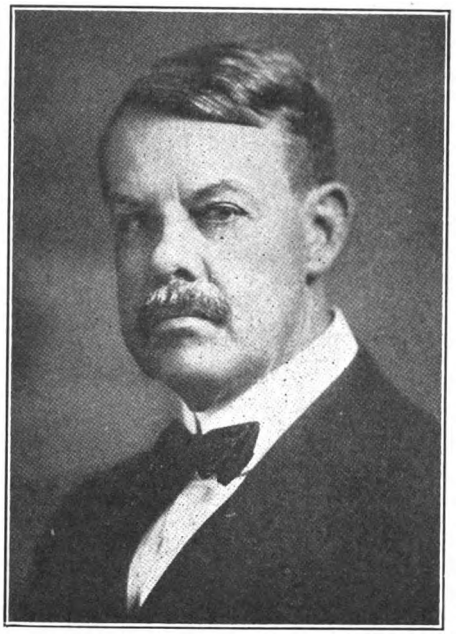
DEAR SIR:

In view of your letter of April 14, we are inclosing herewith Company's check for $———— in payment of your service in connection with the case of ———.

Very truly yours,

LINCOLN NATIONAL LIFE INS. CO.

DEATHS



EDWIN WALKER, M.D., of Evansville, who died April 23, 1922, had been in declining health for the past five years, due to a spinal disease which a laminectomy disclosed to be round-celled carcinoma.

Dr. Walker was born at Evansville, Indiana, in 1853, being sixty-eight years old at the time of his death, and was the son of James T. and Charlotte Walker. He was married to Miss Capitola Hudspeth of Evansville, who survives him. No children were born to Dr. and Mrs. Walker.

His early education was obtained at the Evansville public schools, and later he graduated from Hanover College, from which school he received the degree of Ph.D. He then began the study of medicine, graduating when he was but twenty years of age from the Evansville Medical College in 1874. He also graduated from the New York University Medical College in 1879. Shortly after his graduation in medicine he was made demonstrator of anatomy and

subsequently professor of anatomy in the Evansville Medical College. Later he also held the chair of Diseases of Women, and at one time the chair of Diseases of the Nervous System.

Dr. Walker was a constant student and had made several trips to Europe, on one of which he spent two years in postgraduate work. He was an active worker in medical societies, and has contributed much to the medical literature of his state. He had been first vice-president

Dr. Edwin Walker

of the American Medical Association, president of the Mississippi Valley Medical Association, president of the Indiana State Medical Association (at the time of his election being the youngest physician who had ever held the latter office), and was a member of the first Board of Councilors under the present organization of the society, which position he held for a number of years. He was interested and active in all that pertained to the interests of the medical profession. He was, until the beginning of his present illness, one of the leading abdominal surgeons in Indiana, and his experience and skill were reflected in his papers and discussions in the numerous medical associations to which he belonged. He had an unusual charm of manner and felicity of expression, and was especially well known in the American Medical and Indiana State Medical Associations, in both of which he had an active and sincere interest. Upon the reorganization of the American Medical Association he was a member of the first House of Delegates, and represented the Indiana State Medical Association in that capacity for several years.

Dr. Walker also was interested in civic affairs, and for the past twenty years had been president of the Associated Charities of Evansville. At one time, for four years, he served as a member of the City Council and president of the City Board of Health. He formerly was a member of the board of trustees of the Medical College of Indiana.

Dr. Walker engaged in general practice for several years, afterwards giving his chief attention to surgery, and in 1894, in association with the late Dr. A. M. Owen, he established the Walker Hospital. This hospital has been for many years, and still is, the largest and most successful private hospital in Indiana, and since his illness has been conducted by his staff of nine associates.

As stated editorially by the *Evansville Courier*, if ever a man ennobled a noble art, Dr. Edwin Walker surely graced and adorned his profession. It is given to but few of us to reach the height in his chosen life work that Dr. Walker achieved; it is given to fewer of us to reach the pinnacle and leave only admirers upon the plains beneath—yet that dual achievement may be writ to his everlasting credit. An honored memory is a wonderful heritage, and Dr. Walker's life and work will live on and be an inspiration to those whose privilege it was to know him.

THOMAS A. SHANE, M.D., of Columbus, died April 14 at the age of eighty-two years. Dr. Shane graduated from the Pulte Medical College, Cincinnati, in 1881.

JOHN S. HOLLINGSWORTH, M.D., of Indianapolis, died April 8 at the St. Francis Hospital as the result of an automobile accident. Dr. Hollingsworth was fifty-seven years of age. He graduated from the Medical College of Indiana, Indianapolis, in 1893.

GEORGE A. STEVENSON, M.D., of Rising Sun, died March 30 at the age of eighty-four years. Dr. Stevenson graduated from the Rush Medical College, Chicago, in 1865, and was a member of the Ohio County Medical Society, the Indiana State Medical Association and the American Medical Asociation.

ELIHU P. WASHBURN, M.D., died at his home in Buffalo, Indiana, April 1. Dr. Washburn was eighty years of age and was a graduate of the Medical College of Indiana, Indianapolis. He was a member of the Jay County Medical

Society, the Indiana State Medical Association and the American Medical Association.

MILLARD F. BRACKNEY, M.D., of Mooresville, died April 20 as the result of complications of diseases contracted while in the army. Dr. Brackney graduated from the Medical College of Indiana, Indianapolis, in 1890, and was a member of the Morgan County Medical Society, the Indiana State Medical Association and the American Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in THE JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

THE Benton County Medical Society held its regular monthly meeting at Oxford, March 29.

DR. O. T. BRAZELTON, of Princeton, has been appointed county health officer for Gibson county.

THE Northern Tri-State Medical Association held its forty-ninth annual meeting at Ann Arbor, Michigan, April 11.

THE Howard County Medical Society held its meeting at Kokomo, April 7. A paper was presented by Dr. George D. Marshall.

DR. L. D. GOODWIN has moved to Francisco from Winslow. He will take up the practice of medicine in Francisco.

THE Sullivan County Medical Society held a meeting at Sullivan, April 12. A paper was presented by Dr. V. A. Funk, of Vincennes.

AN electric diet kitchen is being installed in the Indianapolis Orphan Asylum, the gift of Mrs. Bernard Vonnegut.

DR. CHARLES S. WOODS has resigned as superintendent of the Methodist Hospital, Indianapolis.

DR. E. E. HODGIN, president of the Board of Public Health of Indianapolis, has announced that seven internes will be added to the present number (seventeen) at the City Hospital.

DR. W. A. HOLLIS, of Hartford City, has returned from Chicago, where he took some special work on the eye under Professor Fuchs, of Vienna.

DR. BYRON E. BIGGS has been appointed superintendent of the Indiana State School for Feeble-Minded Youth at Fort Wayne by Governor McCray.

DR. F. E. HAGIE, of Richmond, has been appointed surgeon for the Pennsylvania Railroad Company to succeed the late Dr. Charles Marvel.

THE Clinton County Medical Society held its regular meeting at Frankfort, April 6. Dr. L. L. Harding, of Frankfort, presented a paper on "Hyper-Thyroidism".

DR. HERBERT A. RAY, of Fort Wayne, has been selected by the S. F. Bowser Company to fill the place of company physician. He succeeds the late Dr. E. E. Morgan.

DR. W. C. REED, of Bloomington, has been made assistant to Dr. J. E. P. Holland, Indiana University physician. Dr. Reed succeeds Dr. Fernande Hachat Luck.

THE Tippecanoe County Medical Society held its monthly meeting at Lafayette, March 28. A paper on "Some Aspects of Malocclusion" was presented by Dr. Paul A. Risk.

AT the request of a delegation of colored men from Marion County, adequate provision has been made in the county tuberculosis hospital at Sunnyside for the care of negro patients.

AN amputating case, purchased in 1840 and used during the Civil War by the late Dr. Albert G. Preston, has been placed in the state museum at Indianapolis.

THE Huntington County Medical Society held its regular meeting April 4 at Huntington. A paper on "Uremic Poisoning" was read by Dr. R. G. Johnson.

COMMENCEMENT exercises for eighteen nurses of the Lutheran Hospital Training School for Nurses, Fort Wayne, were held May 3.

THE St. Joseph and Epworth Hospitals at South Bend are to be enlarged. The St. Joseph Hospital will erect a new addition that will cost $250,000 and the Epworth will expend $150,000 upon improvements and additions.

AFTER an enforced vacation of more than four months, Dr. G. M. LaSalle has resumed the practice of surgery at Wabash. As the result of an infection Dr. LaSalle was ill for many weeks.

THE Muncie Academy of Medicine held its regular meeting at the Hotel Roberts, Muncie, April 7. Dr. William T. Coughlin presented a paper on "Diagnosis of Surgical Conditions About the Head and Neck".

THE Madison County Medical Society held its regular meeting at the Grand Hotel, Anderson, April 18. A paper was presented by Dr. H. W. Gante, the subject of which was "The Allen Treatment for Diabetes".

DR. WILL SHIMER, of Indianapolis, has resigned as bacteriologist and pathologist for the State Board of Health to become bacteriologist and pathologist for St. Vincent's Hospital and head of its laboratories.

DR. CHESTER N. FRAZIER of the Irene Byron Hospital of Fort Wayne has received an appointment to the Rockefeller Institute, Peking, China. Dr. Frazier is a specialist in skin diseases.

THE Muncie Academy of Medicine held its meeting Friday evening, April 28, at the Hotel Roberts, Muncie. Dr. C. P. Emerson, Indianapolis, presented a paper on "Neuroses of the Twentieth Century".

DR. CHARLES S. WOODS, of Indianapolis, was made president of the Indiana section of the American Hospital Association to succeed Dr. George F. Keiper, of Lafayette, at the annual convention of the Association held April 19.

THE regular monthly meeting of the Kosciusko County Medical Society was held March 28 at Warsaw. "Urinary Stones" was the subject of an address presented by Dr. H. O. Mertz, of Indianapolis.

THE Porter County Medical Society held its meeting at Valparaiso, March 30, at the home of Dr. H. O. Seipel. Dr. Harry E. Mock, of Chicago, presented a paper on "Reconstructive Surgery as Learned from the World War".

DR. R. A. BARLOW, recently associated with the Mayo Clinic, has announced the opening of his office at 461 Farmers' Trust Building, South Bend, for the special practice of diseases of the ear, nose and throat.

THE United States Civil Service Commission announces an open competitive examination for dietitian. Applications will be rated as received until further notice. Applicants should apply at once for Form 1312, to the Civil Service Commission, Washington, D. C.

THE Muncie Academy of Medicine held a meeting at the Hotel Roberts, April 21. "Natural History of Bladder Infections" was the subject of an address presented by Dr. Hugh Cabot of the Michigan University School of Medicine.

THE joint meeting of the Jackson and Bartholomew County Medical Societies was held at Seymour, April 6. A paper on "The History of Endocrinology" was presented by Dr. L. B. Hill, of Seymour, and Dr. Gillespie, also of Seymour, presented a paper on "Obstetrical Problems".

THE Hendricks County Medical Society held its regular quarterly meeting at Danville, April 28. Dr. L. D. Carter, of Indianapolis, talked on the diseases of children and babies, and the care of the baby during summer months. A baby clinic was held in connection with the meeting.

AT the sixth annual meeting of the American College of Physicians, held in Minneapolis, the following officers were elected for the ensuing year: President, Dr. James M. Anders, Philadelphia; vice-presidents, Drs. Frederick Tice, Chicago, and Charles C. Bass, New Orleans; treasurer, Dr. Clement R. Jones, Pittsburgh, and secretary, Dr. Frank Smithies, Chicago.

THE United States Civil Service Commission announces an open competitive examination for Associate in Clinical Psychiatry and Psychotherapy. Applications will be rated as received until July 31, 1922. Applicants should at once apply for Form 2118, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

COL. EDWARD GIBBS, who recently returned from Poland, where he went to study typhus conditions, states that strict precautions are necessary to prevent the scourge from spreading in this country. Dr. Gibbs reports that there were only three thousand physicians to cover the entire thirty million population of Poland, and that typhus is epidemic.

THE United States Civil Service Commission announces open competitive examinations for Laboratorian (bacteriology) and Assistant Laboratorian (bacteriology). Applications will be rated as received until further notice. Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

IT has been announced that a course in diagnosis and treatment of syphilis of the nervous system will be given by Drs. H. C. Solomon and Henry Viets from June 5th to 30th, inclusive, at the Boston Psychopathic Hospital, the Massachusetts General Hospital and the Neuropathological Laboratory, Harvard Medical School. Enrollment is through the Graduate Office at the Harvard Medical School.

THE United States Civil Service Commission announces open competitive examinations for the position of Assistant Medical Officer (psychiatry) and Junior Medical Officer (psychiatry). Applications will be rated as received until further notice. Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

AT the annual meeting of the American Congress on Internal Medicine, held at Rochester, Minnesota, the following officers were elected: President, Dr. Sydney R. Miller, Johns-Hopkins University Medical School, Baltimore; vice-presidents, Drs. Henry S. Plummer, Rochester, Minn., and S. R. Roberts, Atlanta, Ga.; treasurer, Dr. C. R. Jones, Pittsburgh, and secretary general, Dr. Frank Smithies, Chicago.

THE United States Civil Service Commission announces that there is need for nurses in the hospitals of the United States Veterans' Bureau and the Public Health Service and at Indian schools and agencies. Applications will be received for these positions until further notice. Full information concerning entrance requirements, salaries, etc., and application blanks, may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or the secretary of the civil service board at the post office or customs house in any city.

THE Marion National Sanatorium, formerly the Soldiers' Home, National Military Home, Indiana, is being converted into a sanatorium for disabled veterans of the World War suffering from mental or nervous diseases. More than 800 patients are receiving treatment now and there will be room for 150 additional ex-service men when the present changes are completed. A system of schools for the teaching of occupational therapy is provided and the prevocational training is conducted in the wards. Ground has recently been broken for a new eighty-bed tuberculosis hospital which will be opened September 1.

DURING March the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: Abbott Laboratories — Izal; Izal Disinfectant Powder. Intra Products Co.—Ven Sterile Solution Mercury Benzoate 1 Cc. Merrell-Soule Co.—Powdered Protein Milk-Merrell-Soule. Parke, Davis & Co.—Pertussis Vaccine; Pneumococcus Vaccine (4 Types); Streptococcus Vaccine Polyvalent (Scarlatina); Typhoid-Paratyphoid Vaccine (Prophylactic). Seydel Manufacturing Co.—Benzocaine-Seydel. Winthrop Chemical Co.—Iothion; Iothion Oil; Sabromin; Sabromin Tablets 8 Grains. Acriflavine-Heyl; Proflavine-Heyl. These products are now marketed by the National Aniline & Chemical Co. and the Council has continued the acceptance for New and Nonofficial Remedies under the new firm name.

JACKSON, BARTHOLOMEW, JENNINGS

A meeting of the physicians of Jackson, Bartholomew and Jennings counties was held at Seymour on April 6, with 22 physicians present. These union meetings have been held monthly during the past winter, alternating Seymour and Columbus as meeting places.

A banquet was held at six o'clock at the Hotel Fosgate, after which the following scientific program was given: "The History of Endocrinology", by Dr. C. E. Gillespie, Seymour; "Missed Abortion", Dr. L. B. Hill, Seymour.

The next meeting is to be held at Columbus in May.
Adjourned.

L. B. HILL,
Secretary Jackson County
Medical Society.

ELEVENTH DISTRICT

At the October (1921) meeting of the Eleventh Indiana Councilor District Medical Association, Dr. G. R. Daniels, of Marion, offered the following resolution which is to be voted upon at the coming meeting to be held May 18, 1922:

"To amend the Constitution and By-Laws of Art. 3. Sec. 2, by adding: and any member who may not attend the meetings of any year may withhold paying the dues for such year without forfeiting his membership."

Art. 3, Sec. 2, that the above resolution proposes to amend now reads as follows:

Sec. 2. (Amended October 16, 1919, to read:) The membership of this association shall consist of members in good standing of the county societies composing this district, who have paid annual dues into this association on or before the opening of the annual meeting on the third Thursday in May of any current year of its existence."

INDIANAPOLIS MEDICAL SOCIETY

Meeting April 25, 1922

Meeting called to order by the president. Minutes of previous meeting read and approved. Announcement made by the secretary that there would be a dinner meeting of the society on the 9th of May, at which time Dr. Clifford G. Grulee and Dr. Edwin C. Ryerson, both of Chicago, would be the principal speakers. No new business. Unfinished business consisted of the report of Committee on State Medicine, which follows:

Your Committee, firmly believing that the principle of our Government, as enunciated by the Constitution of the United States, "equal opportunity to all and special privileges to none," applies to the relations between the State and the Medical Profession, as well as between the State and other industries; that a free and untrammeled Medical Profession is necessary for the advancement of Medical Science, for the welfare of the Medical Profession and for the health of the people; that the Medical Profession as a whole, and not one physician or group of physicians, is responsible for public, as well as private health; that it devolves upon the Medical Profession directly and indirectly to educate the people to sound thinking on all matters pertaining to health and to guard them against socialistic schemes of selfish individuals and groups, after having considered every phase of so-called State Medicine, have agreed that:

WHEREAS, Your Committee recognizes the right of the State to supervise medical education, to conserve the health and well-being of its citizens, and to that end has the privilege and duty of erecting and maintaining institutions for medical education, for the care and treatment of its indigent population, and has the right and duty of fixing the standard for the proper performance of the Medical Practice Act, and,

WHEREAS, The State has the right and duty to conduct and maintain adequate State and County Health Boards, and insofar as it fulfills all these above indicated rights and duties, should have and does have the unqualified support of the Medical Profession in the fulfillment of these vested rights, which in no sense conflict with the principles hereinafter set forth, and,

WHEREAS, Certain abuses of the above rights and duties, which abuses, if unchecked, will develop into State Medicine, a term which to most physicians and people has meant everything and meant nothing, and which may be defined as the sum of a number of growing evil tendencies not commonly interpreted as having any part in Medical Socialism, and,

WHEREAS, The indicated abuses have been, and are still indulged in, and abetted by the State or its agents, we, therefore, offer the following resolutions as a platform of principles upon which the Indianapolis Medical Society should stand:

RESOLVED:

1. That while the Indianapolis Medical Society heartily supports the proposition that the State should care for its mental and moral defectives, and its indigent sick, it unqualifiedly condemns the tendency of the State to enter into competition with licensed physicians in the practice of Medicine and Surgery, and it condemns the maintenance of pay beds and wards in State Institutions or those partially subsidized by the State.

2. That it condemns the practice of appointing physicians to salaried and advertised positions and at the same time permitting these same salaried officials, free competitive rights against the profession to which they belong, and declares that no person employed in any of its Medical Institutions, Hospitals, or Colleges, either in whole or in part supported by State funds, who occupies a position of trust or a chair of teaching in any department of Medicine or Surgery and who receives pay or salary for such employment, should be accorded the privilege of private medical or surgical practice, so long as such person is employed by the State and receives pay for services from any State funds of whatsoever character.

3. That it commends the establishment of free clinics for the treatment of tuberculosis, mental hygiene, venereal, and other diseases of the indigent sick, but for no other than the indigent.

4. That it endorses in public health administration, full time salaried officers who shall not, during their service, have the privilege of private practice, nor any right of supervising private practice.

5. That it upholds the standard and purpose of the State Medical Practice Act and insists that all persons engaged professionally in the treatment of diseases, or the sick, whatsoever, of any description, shall be wholly subject to the same standard of educational qualifications and State examinations.

6. That while, at the present time, it recognizes the necessity of certain societies and industrial development to maintain adequate medical and surgical staffs, it deplores the growing tendency to widen the scope of contract and similar medical and surgical practice wherein the profession is not remunerated according to the usual competitive method and the patient not permitted to use his own selection of physicians.

7. That it condemns legislative enactments relative to all health matters, without the sanction and approval of the licensed and registered Medical Profession.

8. That it opposes lay and political domination of Medical and Surgical practice as opposed to sound public policy and to the scientific progress of medicine.

9. That, while it endorses the efforts of the agents of the Federal and State Governments in their desire to promote the health of the people, it condemns Federal supervision of State medical activities, masquerading under the guise of Federal aid or subsidy.

10. That it condemns the socialistic efforts of State, Federal, County or Municipal agents, to force the expense of private health upon the taxpayers, under the guise of Public Health.

11. That it condemns all "propaganda and elements at work" to create fictitious health problems, as attempts to socialize the Medical Profession, under the plea of "suffering humanity", whereby a great part of an independent people would be segregated into a pauperized class.

12. That it condemns the exploitation of special fields of medicine, surgery and obstetrics, by technicians, who are not qualified, licensed physicians.

Recognizing that the successful treatment of sick people depends upon personal and confidential relations between physician and patient, which relations are impossible under any of the indicated evils; and knowing humanity in its strength and in its weakness, in health and in disease, in wealth and in poverty, we, who dedicate our lives to the scientific investigation, prevention, and treatment of disease, with firm conviction in the ultimate wisdom of our course, offer these resolutions, and pledge our best efforts to uphold all true American ideals and principles.

BE IT FURTHER RESOLVED, That a true copy of these resolutions be immediately sent to the Secretary of each County Medical Society of the State of Indiana, to the Editor of the JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION, and to the Editor of the *Journal of the American Medical Association*.

FREDERICK E. JACKSON, M.D., Chairman,
JOSEPH RILUS EASTMAN, M.D.,
W. B. KITCHEN, M.D.,
THOMAS B. NOBLE, M.D.,
ALBERT E. STERNE, M.D.,

Committee on State Medicine,
Indianapolis Medical Society.

Each paragraph of the above resolutions was fully discussed by the Society, a motion made and carried to adopt each separate paragraph, after which a motion was made and carried to adopt the resolutions in their entirety.

THE TRUTH ABOUT MEDICINES

NEW AND NONOFFICIAL REMEDIES

AMMONIUM ICHTHYOLATE-MEADOWS.—An aqueous solution, the important constituents of which are ammonium salts of indefinite, complex, organic acids, partaking of the nature of oxygenated bodies and sulphonates held in colloidal dispersion. It is derived from an oily distillate of a fossiliferous bitumen found in Texas. It is claimed that ammonium ichthyolate-Meadows has the therapeutic properties of ichthyol. (See New and Nonofficial Remedies, 1921, p. 344.) It is a reddish-brown, viscous fluid, having a faint odor. It is soluble in water and miscible with glycerine and fatty vehicles. Meadows Oil and Chemical Corporation, Durant, N. Y.—(*Jour. A. M. A.*, April 1, 1922, p. 967).

QUINIDINE.—QUINIDINA.—An alkaloid obtained from the bark of various species of Cinchona. Quinidine acts upon the heart in such a manner as to bring about cessation of fibrillation of the auricles in a certain proportion of instances. It is used to restore the normal rhythm of the heart in cases of auricular fibrillation. The drug is not without unpleasant and even dangerous effects. Cases of sudden death from its use have been reported. Quinidine is generally administered as quinidine sulphate. Two-tenths gm. given as a preliminary dose. If no untoward effects result, the drug is administered on the following day in doses of from 0.2 to 0.4 gm., from three to five times a day and continued for from one to three days.

QUINIDINE-P. W. R.—A brand of quinidine-N. N. R. Powers-Weightman-Rosengarten Co., Philadelphia.

QUINIDINE-N. Y. Q.—A brand of quinidine-N. N. R. New York Quinine and Chemical Works, New York.

QUINIDINE-M. C. W.—A brand of quinidine-N. N. R. Mallinckrodt Chemical Works, St. Louis.

QUINIDINE SULPHATE.—QUINIDINAE SULPHAS.—The sulphate of quinidine. For actions, uses and dosage, see under quinidine. It may be administered in the form of cachets, capsules, pills or tablets.

QUINIDINE SULPHATE-P. W. R.—A brand of quinidine sulphate-N. N. R. Powers-Weightman-Rosengarten Co., Philadelphia.

QUINIDINE SULPHATE-N. Y. Q.—A brand of quinidine-N. N. R. New York Quinine and Chemical Works, New York.

QUINIDINE SULPHATE-M. C. W.—A brand of quinidine sulphate-N. N. R. Mallinckrodt Chemical Works, St. Louis. (*Jour. A. M. A.*, April 8, 1922, p. 1051).

BENZOCAINE-SEYDEL.—A brand of benzocaine-N. N. R. (See New and Nonofficial Remedies, 1922, p. 39). The Seydel Manufacturing Co., Jersey City, N. J.

VEN STERILE SOLUTION PROCAINE 1 CC.—Each ampule contains 1 Cc. of a 1 percent solution of procaine-N. N. R. (See New and Nonofficial Remedies, 1922, p. 35.) Intra Products Co., Denver, Colo.—(*Jour. A. M. A.*, April 22, 1922, p. 1201).

VEN STERILE SOLUTION MERCURY BENZOATE 1 CC.—Each Cc. contains mercuric benzoate, 0.02 Gm. (1/3 grain). (See New and Nonofficial Remedies, 1922, p. 192.) Intra Products Co., Denver, Colo.

TABLETS OF MERCUROCHROME-220 SOLUBLE.—Each contains 4.6 grains. (See New and Nonofficial Remedies, 1922, p. 187.).—(*Jour. A. M. A.*, April 29, 1922, p. 1296).

STERILE SUSPENSION MERCURY SALICYLATE IN CACAO BUTTER 1 CC.—Each Cc. contains .097 Gm. (1½ grains) of mercuric salicylate. (See New and Nonofficial Remedies, 1922, p. 193.) Intra Products Co., Denver, Colo.

STERILE SUSPENSION MERCURY SALICYLATE IN OLIVE OIL 1 CC.—Each Cc. contains 0.097 Gm. (1½ grains) of mercuric salicylate. (See New and Nonofficial Remedies, 1922, p. 193). Intra Products Co., Denver, Colo.—(*Jour. A. M. A.*, April 29, 1922, p. 1296).

PROPAGANDA FOR REFORM

"PREMEDICATED" ALCOHOL.—A petition to permit the use of so-called "premedicated" alcohol in remedies for internal use has recently been placed before the Secretary of the Treasury and the prohibition officials. According to drug journals, such a petition was presented by the Counsel for the Proprietary Association—the organization of the "patent medicine" interests—and also by the Chattanooga Medicine Company—the makers of "Wine of Cardui". When thus medicated, the alcohol is to be tax free. This proposition contains dangers to medicine and to pharmacy in that it may render scientific control of such medicaments difficult.—(*Jour. A. M. A.*, April 1, 1922, p. 970).

NEPHRITIN, PEPTENZYME, TROPHONINE AND PANCROBILIN.—Sometimes the results of the application of the esthetic arts to commercial interests is incongruous. A house organ uses the names of famous writers, presumably to attract attention. Thus: It is suggested that if the physicians to Montaigne, who died of nephritis, had known of "Nephritin" they would have been able to furnish him with "substantial constructive help"—a statement which may be more readily accepted by litterateurs than by pathologists. Since all of us cannot live the simple life recommended by Joaquin Miller, as a means of avoiding indigestion, it is inferred that we must depend on Peptenzyme. It is related that Thomas Hood passed away in spite of soups and other nourishing food prepared for him by his wife. "Therefore," says the advertiser, "use Trophonine and live." "Like Victor Hugo," proclaims the advertiser, "millions today are eating the unknown and are paying the toll in constipation." He further asserts, "From whatever cause it originates—Pancrobilin is always indicated". Alas, Nephritin, Peptenzyme, Trophonine and Pancrobilin cannot avail Montaigne, Miller, Hood or Hugo now.—(*Jour. A. M. A.*, April 1, 1922, p. 971).

LEAVEN'S ASTHMA PRESCRIPTION.—This is put on the market by the Leavengood Drug Co., Rosedale, Kansas. The A. M. A. Chemical Laboratory reports that the composition of this preparation is essentially: Potassium iodide, 10.9 Gm., sugar (sucrose), 55.0 Gm., iron, a trace, water, flavoring and coloring matter to make 100 Cc.—(*Jour. A. M. A.*, April 1, 1922, p. 991).

EKSIP.—This is a mail-order "cure" for diabetes, marketed by Matthew Richartz with the slogan, "No more dieting! No more starving! 'Eat and get well!'." Eksip is sold in the form of tablets at $6.00 for 200. The A. M. A. Chemical Laboratory reports that the bulk of the tablets consisted of magnesium carbonate and starch. A small quantity of an unidentified drug was found. Alkaloid, heavy metals and emodin-bearing drugs were absent.—(*Jour. A. M. A.*, April 1, 1922, p. 991).

"PROPRIETARY PREPARATIONS IN POLAND".—The influence of the work of the American Medical Association—through its Council on Pharmacy and Chemistry and *The Journal's* Propaganda for Reform in Proprietary Medicines—in protecting the public, both directly and indirectly, against the nostrum evil, extends year by year. Especially is it noticeable when new legislation is created. Recently, the new Polish state introduced regulations governing the

(Continued on Adv. p. xx.)

The Endocrines, Digestive Ferments, Catgut Ligatures, etc.

THE ARMOUR LABORATORY is maintained for the purpose of handling the glands, membranes and other raw materials supplied by our abattoirs in immense quantities, from which important therapeutic agents are extracted and fabricated.

Among the products that the physicians and surgeons use daily are:

Corpus Luteum; Suprarenals, U. S. P.; Parathyroids; Pituitary, Whole Gland; Pituitary, Anterior; Pituitary, Posterior; and other glandular substances in po. and tabs. Pituitary Liquid in 1 c. c. and ½ c. c. ampoules.

Armour's LABORATORY PRODUCTS

Suprarenalin Solution 1:1000; Suprarenalin Ointment 1:1000; Pepsin, U. S. P.; Pancreatin, U. S. P.; and other preparations of the Digestive Ferments that are used in stomachic and intestinal disorders and as vehicles for nauseating drugs.

We also make Sterile Surgical Catgut Ligatures, plain and chromic, boilable; and Iodized Ligatures, nonboilable. ¶The Armour ligatures are made from Lambs' gut; selected especially for surgical purposes and sterilized at opportune stages in such manner as to preclude the possibility of contamination in the finished strings.

We are headquarters for the Organotherapeutic Agents and are always glad to co-operate with the medical profession

Pharmaceutical Chemists

BALTIMORE, MARYLAND

(Continued from p. 184.)

manufacture and sale of proprietary remedies. These regulations reflect the change in attitude that has taken place in the public mind in all civilized communities toward the responsibility of those who would make and sell preparations of the home remedy type. The Polish regulations have much in common with recent Austrian and Spanish legislation on proprietary medicines, and the influence of the English Proprietary Medicines Bill is apparent in the prohibition of the use of testimonials. While no quantitative disclosure on the label of the composition of the preparation is required, except in the case of potent drugs, the fullest details are demanded from the manufacturer, this information to be of such a nature as will enable the State Pharmaceutical Institute to prepare the preparation for the purpose of verifying the manufacturer's statements. The obligation of the manufacturer to keep a record not only of his production, but of all his supplies to wholesalers, is also a new feature.—(*Jour. A. M. A.*, April 8, 1922, p. 1071).

YEAST FOAM TABLETS.—Shorn of verbiage, "Yeast Foam Tablets" are claimed to be dried yeast in the form of tablets. They are put up in typical "patent medicine" style. The advertising for these tablets would lead the public to believe that it is in imminent danger of suffering from an inadequate supply of vitamin B. Though the Yeast Foam propaganda is plainly addressed to the public, specimen packages have been sent to physicians. Thus, the profession is given once more the opportunity to act as an unpaid peddler.—(*Jour. A. M. A.*, April 8, 1922, p. 1074).

HORMOTONE.—This is a "pluriglandular tonic for asthenic conditions", sold by the G. W. Carnrick Co. in the form of tablets for oral administration. Each tablet is said to contain 1/10 grain of desiccated thyroid, 1/10 grain of entire pituitary, together with the hormones of the ovary and testes—the amount and the form in which the latter are supposed to be present are not given. The Council on Pharmacy and Chemistry refused to accept Hormotone for New and Nonofficial Remedies.—(*Jour. A. M. A.*, April 8, 1922, p. 1074).

QUEEN OF ANTISEPTICS.—This preparation is marketed by a person in Aurora, Illinois, calling herself "Mme. Leonard". It is claimed to be "A Perfect Vaginal Germ Destroying Powder and Applicator". The A. M. A. Chemical Laboratory reports that the preparation is composed essentially of boric acid, 97 percent, and ammoniated mercury 3 percent.—(*Jour. A. M. A.*, April 8, 1922, p. 1072).

YEAST PREPARATIONS AND VITAMIN-B CONCENTRATES.—The Council on Pharmacy and Chemistry has adopted the following principles as a guide in the consideration of yeast preparations and vitamin B concentrates for New and Nonofficial Remedies: 1. The claim that deficiency of vitamin B and diseases resulting therefrom are common conditions in the United States is not at this time warranted. 2. The claim that yeast preparations or extracts are, in principle or in general, essentially more effective or more practical or a more available means of administering vitamins than the commonly available vitamin containing foods is not at this time supported by adequate acceptable evidence. 3. The claim that therapy with yeast or yeast preparations has as yet more than an experimental status is not at this time supported by adequate acceptable evidence.—(*Jour. A. M. A.*, April 15, 1922, p. 1146).

THE THERAPEUTIC USE OF YEAST AND VITAMIN PREPARATIONS.—Newspapers and magazines contain gratuitous reminders that we are confronted with menaces to health which not only ought to be averted but which can readily be remedied, when present, by the simple expedient of a potent proprietary vitamin preparation. If some of the claims of the advocates of a widespread yeast or vitamin therapy regarding the danger of vitamin starvation were warranted, one might still question whether the special "concentrated" or vitamin-rich medicaments were required to remedy the situation. An extensive inquiry has led the Council on Pharmacy and Chemistry to the deduction that disease states attributable to lack of vitamin B are not widespread in this country at the present time. Even an enthusiast will be forced to agree with the Council that yeast or yeast vitamin therapy has as yet nothing more than an experimental status.—(*Jour. A. M. A.*, April 15, 1922, p. 1127).

KOLOR-BAK.—This is a hair dye marketed by the Hygienic Laboratories, Chicago. It is claimed not to be a dye or stain but to restore gray hair to its original color. It is claimed to be harmless and not to contain powerful mineral ingredients. The preparation was analyzed in the A. M. A. Chemical Laboratory and was found to contain lead acetate, 0.6 Gm., and precipitated sulphur, 1.0 Gm., in 100 Cc. It is evident from the analysis that the claims made for Kolor-Bak are false.—(*Jour. A. M. A.*, April 15, 1922, p. 1146).

MORE MISBRANDED NOSTRUMS.—The following proprietary preparations have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act:

DIEMER'S MANHOOD TABLETS (Dr. F. W. Diemer Medicine Co.), consisting chiefly of sodium bicarbonate, reduced iron, a compound of zinc, phosphorus and small amounts of capsicum, strychnin and an extract from a laxative plant drug.

SANTAL-MILLER (General Drug Co.), consisting essentially of San-tal oil and claimed to relieve or cure gonorrhea.

LONG'S KIDNEY AND BLADDER REMEDY (Wm. T. Long Medicine Co.), capsules containing phosphorus, extractives of damiana and nux vomica.

BANES' FEMALE PILLS (Dr. A. V. Banes Medicine Co.), consisting essentially of compounds of calcium, magnesium and iron, and mercury, capsicum, sugar and aloes.—(*Jour. A. M. A.*, April 15, 1922, p. 1146).

SA-TAN-IC (Sa-Tan-Ic Medicine & Mfg. Co.), containing magnesium sulphate, cascara bark extractives, salicylic acid, methyl salicylate, oil of peppermint, water and a trace of alcohol, claimed to be a blood purifier, system renovator and a remedy for stomach, kidney and liver complaints.

BANES' KIDNEY AND RHEUMATIC REMEDY (Dr. A. V. Banes Medicine Co.), containing sodium and potassium compounds of iodine, acetic acid, nitric acid and salicylic acid, vegetable extractive matter, sugar, alcohol and water.

SILVERSTONE'S SEXUAL PILLS (S. Pfeiffer Mfg. Co.), consisting essentially of plant extractives, including resins, nux vomica, alkaloids and damiana.

NUX-AURO-PAPANAD, pills containing strychnin, salts of zinc, calcium and lithium and creosote, claimed to be indicated in Vaso-Motor Paresis, Neurasthenia, Melancholia, Malnutrition, General Debility and Sexual Exhaustion.

PAULETTE'S BRAND TANSY TABLETS (Fay & Youngs Rubber Corp.), claimed to be the most reliable tablets known for the suppression of the menstrual function.

EELLS' VITALIZING BLOOD PURIFIER (F. Eells & Sons Co.), a water-alcohol solution consisting essentially of sugar, Epsom salt, laxative plant material and traces of oil of wintergreen and oil of sassafras.

LE SIEUR'S SYRUP OF TAR AND COD LIVER EXTRACT (Ocean Mills Co.), containing chloroform, menthol, oil of tar, ammonium salts, sugar, water, and a small quantity of alcohol.—(*Jour. A. M. A.*, April 22, 1922, p. 1218).

CALCREOSE

CALCIUM IN INTESTINAL TUBERCULOSIS

"The administration of calcium chlorid in tuberculous diarrhea is, we believe, based on empiricism, but of its good effects there are at present many undeniable examples. . . . We have used calcium chlorid in no sense as a curative agent, but merely as a palliative in an attempt to control the distressing symptoms of pain and diarrhea."—P. H. Ringer and C. I. Minor, Am. Rev. Tuberc. 5:876 (Jan.) 1922.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal parts of creosote and lime.

CALCREOSE has the same actions and uses as creosote but is free from its untoward effects on the stomach. Creosote is used as an intestinal antiseptic.

OSTITIS FIBROSA CYSTICA*

A PATHOLOGICAL CONSIDERATION

VIRGIL H. MOON, M.D.
INDIANAPOLIS, INDIANA

Ostitis fibrosa cystica, often spoken of as ostitis fibrosa, is a more common disease than is generally supposed, as is evidenced by the fact that three cases have come under our observation in less than a year's time. The essential features of this condition were probably first accurately described by von Recklinghausen in 1891, hence the disease is sometimes known under the name of von Recklinghausen's bone disease. The salient characteristics of the disease consist in a proliferation of fibrous tissue in the medullary cavities of the long bones, accompanied by absorption of bony substance resulting in rarefaction, moderate enlargement, and weakening of the bone. Usually but not regularly cyst formation is a prominent feature. It is a disease of childhood and youth, the great majority of cases occurring before the age of twenty. It is suggested as probable that those cases occurring after full maturity developed during youth and remained unrecognized until some years later. The disease is insidious in onset, usually painless, and produces few early symptoms. It most frequently happens that attention is first called to the condition by the occurrence of a spontaneous fracture, or by one resulting from unusually slight injury.

Bloodgood gives the frequency of occurrence in different bones in the following order: humerus, femur, tibia. Muller, in reviewing all the cases of which he had record, found the frequency of occurrence in the order: femur, tibia, humerus. Of the three cases here reported, two were in the femur and one in the tibia. The metacarpal and phalangeal bones are occasionally involved, but the occurrence in other bones is rare.

Microscopically the marrow substance is displaced by a uniform growth of fibrous tissue of a peculiar type. This occupies the entire marrow space, extends into the canals and lacunæ of the compact bone and separates the lamellæ of the hard, bony shell. There is absorption of calcareous material, leaving only a very thin outer shell of the shaft. The periosteum is intact and apparently unaffected. Giant cells are not numerous but are occasionally seen. These are of the type of osteoclasts or of foreign body giant cells rather than resembling those of giant-celled sarcoma. Occasionally small islands of cartilage cells are found embedded in the fibrous tissue or in cysts near the epiphyses.

Cyst formation is a frequent and much discussed feature of the condition, but is not present in all cases. The fluid of the cysts is not under marked pressure and is thin and of a yellowish, reddish or dark brown color. It contains varying amounts of blood cells and pigment, but according to Bloodgood is not distinctly hemorrhagic. The cysts may be single or multiple and may or may not have a distinct limiting membrane. In an analysis of 69 collected cases, all having the character of ostitis fibrosa as shown by the characteristic proliferation of fibrous tissue and by the accompanying rarefaction, Bloodgood found the following variations in regard to cyst formation: (1) A single cyst with bony shell but no connective tissue membrane or lining, 22 cases; (2) a single cyst with definite connective tissue lining of varying thickness, 6 cases; (3) a small cyst or cysts within a solid mass of ostitis fibrosa, 6 cases; (4) no cyst, but the bony shell filled with a solid mass of ostitis fibrosa, 7 cases; (5) multilocular cysts, 6 cases; (6) a miscellaneous group in which the data were incomplete or the cases complicated by the presence of other disease condition, 12 cases.

It is noteworthy that in the above group only a small number, about 10 percent, were purely ostitis fibrosa without cysts. In only one of the three cases which we have seen was cyst formation a feature. Lewis believes that degeneration of the proliferated fibrous tissue, with resulting liquefaction may give rise to the cysts.

Grossly the intact periosteum, the character of the cyst fluid, and the peculiar fibrous character of the medullary substance are stated to

(*) Presented before the Section on Surgery of the Indiana State Medical Association, Indianapolis session, September, 1921.

be of diagnostic value, on exploratory incision, in differentiating ostitis fibrosa from sarcoma.

ETIOLOGY.—The etiology of ostitis fibrosa is entirely obscure. Only a brief summary will be given of the various explanations offered. Many regard it as the result of some injurious agent or irritation. The statement is occasionally found, both in English and in German literature, that if the bone marrow is analogous to a parenchymatous organ such as the liver, ostitis fibrosa might be compared to cirrhosis. This analogy is not perfect since cirrhosis is general throughout the organ and there remain recognizable liver cells between the strands of fibrous tissue, while in ostitis fibrosa the condition is local, and where perfectly formed there are no recognizable remnants of marrow substance. Furthermore, ostitis fibrosa does not confine itself to the marrow spaces of the bone but invades the dense bony shell, causing separation, absorption and rarefaction of the lamellæ. Bloodgood describes the fibrous tissue as inflammatory in nature, and the term ostitis fibrosa itself implies inflammation of bone with fibrous proliferation, but no one as yet has presented evidence as to the character of the injurious agent or irritation which calls forth this proliferation of fibrous tissue.

Various disturbances of metabolism and abnormalities of endocrine function have been thought of as causes. But a metabolic deficiency or abnormality should exert its influence rather diffusely throughout the skeletal system, whereas ostitis fibrosa is a local, not a general, condition. Occasionally ostitis fibrosa occurs in one having a history of previous systemic disease such as rickets. This was true in one of the cases here reported, but such is not of sufficient frequency to be of significance. No hereditary nor familial occurrence has been noted, and there is no evidence of the occurrence in one sex more frequently than in the other.

Ostitis fibrosa is often indexed among tumors, which is probably as much for the sake of convenience as it is for definite evidence of neoplastic character. In the sections which I have studied microscopically the cells resemble a purposeless uniform proliferation of connective tissue, rather than granulation tissue resulting from the action of any injurious agent. Some slight infiltration with inflammatory cells, of mononuclear type, is present in some areas but no more than is frequently seen in areas about benign tumors. Ostitis fibrosa yields readily to surgical treatment where the involvement is not too extensive. Incision and curettage of the involved medulla, in suitable cases supplemented by bone grafts, frequently interrupts the course of the disease and a return to normal condition follows. Obviously such a procedure cannot be expected to remove all the overgrowth of fibrotic tissue, and in this particular the disease presents a striking contrast to neoplasms for neoplastic growth does not subside upon partial removal. No metastases are formed, and the course of the disease would mark it as unquestionably benign should we assume it to be a neoplastic growth. Benign neoplasms usually have a capsule and regularly have a sharply defined margin of growth. These features are conspicuously absent in ostitis fibrosa, for the lesion has an indefinite margin and the growth of fibrous tissue is distinctly infiltrative in character. Should this disease be admitted as a neoplastic growth it would almost belong in a class by itself, since it has few features in common with other neoplasms.

Some authorities believe that by a process of metaplasia the bony tissue has given rise to a proliferation of cells of a fibrous tissue character. This view probably has as many supporters as has either of the other attempted explanations, notwithstanding that modern pathologists are very conservative concerning the possibility of a fixed tissue undergoing a metaplasia into a distinctly different type of cells.

In the first case reported by Dr. Oliver the x-ray pictures taken at intervals of months during a period of years showed a progressive involvement extending finally throughout the shaft of one femur and appearing later in the upper end of the opposite one. We believed this might be an obscure infection with some organism of low virulence. Acordingly the following procedures were instituted: Dr. Oliver performed incision and curettage of the recently involved femur, using most careful precautions to exclude contaminating organisms. No cysts were found, so scrapings from the involved medulla were planted in a wide variety of specially prepared culture media. Among these were dextrose-serum-agar containing bits of fresh bone medulla obtained aseptically from the ribs of a young dog. Others contained splenic pulp similarly obtained. Serum-broth similarly enriched with fresh living tissue was also used. Tubes so prepared were incubated both aerobically, anaerobically and with partial exclusion of oxygen. No bacteria of any kind grew in any of the tubes in a period of two weeks during which daily observations were made.

Portions of the involved bone from two of the cases here reported were sectioned and prepared with stains for bacteria. A careful microscopic search resulted in no organisms of any kind being found in any of the sections. These results coincide with those of others who have had negative results in attempting to demonstrate bacterial infection as a causative factor in ostitis fibrosa.

A further discussion of the etiology of ostitis fibrosa is not profitable at this time. It remains

one of the few diseases in which progress in diagnosis and treatment has far outstripped an understanding of the nature of the cause.

BIBLIOGRAPHY

For complete bibliography of ostitis fibrosa see:

Bloodgood: Annals of Surg., 1910, LII, 145-185.
Lotsch: Arch. f. klin. Chir., Berlin, 1915, CVIII, 1—137.

DISCUSSION

DR. CHARLES M. MIX (Muncie): The outstanding thing in the clinical diagnosis of this condition is the fact that practically all of these cases will come to their physician with a history of fracture without trauma. Such cases of course are subjected to the x-ray now and peculiar conditions are found which should lead to correct diagnosis. The x-ray is a very important feature, and of course the pathological examination makes the diagnosis complete.

Perhaps it is not wise to theorize or comment much on the etiology of this condition which is admitted not to be definitely settled, and likewise the nature of the pathology. I would like to make this comment, however. In dealing with fractures and with osteomyelitis, with sarcoma, with lues or syphilis of the bone, we have two processes going on there simultaneously or at different periods—a rarefying process and a productive process. I think we can safely say that in ostitis fibrosa we have a disturbance in the normal metabolism of the bone —perhaps that is not exactly the right word, but there is a disturbance of the normal growth of the bone. We have in this condition a rarefying process beyond the normal in the formation of the cyst, and we have a proliferating process which produces a fibrous tissue.

In regard to the treatment, we are not likely to get into many difficulties. Apparently almost anything you do helps. A pathological fracture apparently has a tendency to initiate a cure. A curettage and thorough scraping out certainly starts a process which tends toward cure. So if we can differentiate this from sarcoma we are pretty safe, and we are still safe because any radical operation for sarcoma of the bone has been abandoned. So even then your palliative treatment helps. I just wonder, inasmuch as this is a fairly new condition and diagnosis of bone tumor is obviously difficult, if some of the cases which Coley reports as cured by the use of his toxin, may not have been cases where diagnosis was wrong and we might have been dealing with some such condition as this.

DR. G. D. MARSHALL (Kokomo): In noting the radiographs thrown on the screen there was but one that seemed a typical ostitis fibrosa. Ostitis fibrosa is usually more uniform in outline. Most cases involve the shaft and the enlargement of the bone is more fusiform than the cases we have seen here.

The etiology of ostitis fibrosa or of bone cyst is a matter of considerable conjecture. In ostitis fibrosa, Jones suggests that the treatment be a multiple-longitudinal incision of the periosteum with relief of weight bearing on the bone.

Personally, I think most of these cases are the result of focal infection. I have had a case in my own practice in which the woman had been subject to long continued pelvic infection with involvement of the phalanges. This evidently had been a proliferative inflammatory condition with decalcification of the bone which led to cyst formation, and this condition followed by eburnation of bone. This patient had a chronic salpingitis. The right tube was a pus sack, with the periodical evacuation of pus from this pyosalpinx. So she had been subject to continued infection.

PUERPERAL ECLAMPSIA*

JANE KETCHAM
INDIANAPOLIS

Puerperal eclampsia is one of those diseases so dramatic and so terrifying in their effect that the question of the nature of the disease has always been overshadowed by the question of treatment. The first and very natural thought of almost every obstetrician is, since this disease is bound up with pregnancy, "What is the best way to terminate the pregnancy, thereby curing the disease." This attitude is wrong. In the first place some of the most terrible cases of eclampsia have come up following delivery; there apparently having been no prodromes. Moreover, there are many cases where a very rapid delivery has seemingly not influenced the eclamptic condition in any way. Entirely aside from the question of whether to treat the disease according to the radical or conservative method, nothing will really be learned of this dreadful condition until much more is done in the study of these fulminating cases. The three questions which should be taken up are. (1) What is the nature of eclampsia? (2) How may it be foreshadowed or prevented? and (3) How shall it be treated when it has reached its terrifying climax?

In the first place, what is the nature of eclampsia? The popular theory is that it is indissolubly bound up with nephritis. It remains to be seen whether or not this is true. Every medical student knows that urine of the gravida should be examined frequently in order to forecast eclampsia. It does not take very much experience to discover that many cases of eclampsia are ushered into full bloom with the merest traces of albumen, and that many a woman carries albumen and granular casts chronically and does not become eclamptic. On the other hand we have seen cases of florid

(*) Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

eclampsia who give a history of scarlet fever in infancy, no evidences of nephritis in the intervening time with the eclamptic attack many years following—the history of early nephritis having been all but forgotten. It may be that careful prenatal observation will be able to correlate these diverse findings; but to date, about all we have to go on is preparedness and watchful waiting.

In many women, the entire metabolism seems perverted, from the time of impregnation until they are relieved of what seems to be a foreign body. Whether this is a true protein poisoning or an endocrine disturbance is yet to be worked out. Much work is being done and the advocates of the endocrine theory think that much can be done by supplying various hormones. I will say that the very worst case of eclampsia I have ever seen was a young girl of 19 years, who had a complete thyroid extirpation when she was 13 years old, and it was very evident that she was suffering from a thyroid deficiency. The usual treatment of eclampsia suggests that the profession in general has the opinion that the origin of this trouble is in the intestinal tract, and certain it is that the premonitory symptoms are relieved, if not cured, by prompt attention to the emunctories. However, we cannot say that auto-intoxication explains the fulgurant cases of eclampsia, which are so sudden in their onset and so fatal. In 1911, Abderhalden presented his theory that the syncytial cells are thrown into the blood stream from the placenta, and that in normal blood a hemolytic ferment is developed which digests these cells, that where this ferment is not developed a protein poisoning develops. Thus we have three unproved occasions for eclampsia, which are: the overwhelming of the system by massive intestinal intoxication, the endocrine disturbances, and the lack of development in the blood of a proper defense to the cells thrown from the placenta.

Which leads me to the second phase of my subject: How may eclampsia be foreshadowed? The routine examination of urine is no new thing and needs no advocate. Albumen in the urine in the voided specimen means little or nothing. The presence of casts, especially of the granular type, is much more disquieting. The 24 hour quantity should be frequently measured and compared with the intake. After trouble has developed and the patient is in the hospital, this comparison of output and intake should include the approximate measurement of the water content of the stools. This is important. The blood pressure should be taken at frequent intervals and furnishes one of the best indicators of impending trouble. It is desirable, even if no trouble comes, to have an idea of what the patient's normal reading is. Along this same line it is routine to have at least one phenol-sulphone-pthalein test before the onset of labor. The patient should be often asked as to her vision, and her eye-grounds often examined. Retinal exudates and hemorrhages are among the most classical signs of impending eclampsia. The subjective signs the women complain of are bladder irritability, which includes scantiness and frequency, pain, etc.; headaches, and swellings which are not important as long as confined to the feet, but when found in the hands and face are very important; black spots before the eyes, and drowsiness. The objective signs are mounting blood pressure, chemical and microscopic pathological condition in the urine, and positive eye signs. These signs do not differentiate between true eclampsia and uremia, and indeed only the clinical course and the response to treatment are the means we have found, so far, of differentiating true and spurious eclampsia. There is no reason why a nephritis, chronic in type and due to an old scarlet fever, to repeated attacks of tonsilitis, to bad teeth or chorea, or to the thousand and one causes for nephritis, might not be an underlying occasion for kidney deficiency, to which the added burden of pregnancy might mean a serious breakdown of the kidneys, but that is not true eclampsia. On the other hand, we often find placentæ with infarcts where there has been the possibility of a long absorption of dead placental tissue into the general circulation with consequent protein poisoning.

There are two classical treatments for eclampsia, and each has ardent advocates; the conservative and the radical. Edgar, *A. M. A. Journal*, August, 1919, declares that 8 to 10 percent of eclamptics die regardless of treatment, and that 80 to 90 percent will recover under conservative treatment, which does not include shock producing operations nor shock producing drugs. The conservative treatment hopes to give the patient time to recover from her toxemia before emptying the uterus, and the radical advocates declare that the toxemia will not be relieved until the uterus is emptied; therefore, they demand as early emptying as is compatible with safety. My thought is this: We are dealing with a disease the causation of which we do not know. We do know, however, that the mortality is high both for the mother and the child. We know that in all probability the primipara will empty slowly if left to her own devices, and that equally probable, the multipara will be much quicker. We must not overlook the possibilities of uterine inertia, however, in either case. We also recognize the child as a foreign body, and in the presence of a mounting systolic pressure we know we cannot delay too long. If there ever was a disease where we are to be justified in treating each case as an individual this is the disease.

The conservative treatment is outlined by Dr. Ross McPherson of New York as follows: Take the blood pressure. Wash out the stomach and before withdrawing the tube introduce two ounces of castor oil. Give colon irrigations of five gallons of 5 percent glucose solution and control convulsions by administration of large doses of morphine. The initial dose is one-half grain, repeated in one-fourth grain doses until the respirations fall to 8 per minute and convulsions are under control. If systolic pressure is 175 mm. Hg or over, phlebotomy is practiced until the pressure reaches 150 mm. Hg. Under this method he claims in 67 true convulsive toxemias the mortality showed a maternal mortality of 7.4 percent and a fetal mortality of 28.59 percent. While under radical treatment maternal mortality is 30 percent and fetal mortality is 40 percent. The danger of morphinism to the mother is not so great as might be expected as the uterine contractions tend to bring out the patient; it is, however, very hard on the child if delivery is effected before the effect of the morphine wears off, asphyxia resulting.

The radical emptying of the uterus is followed by every possible means of elimination. Cæsarian section is, undoubtedly, the quickest means of emptying the uterus, and is, in certain cases, justifiable; but it is also undoubtedly one of the most serious of operations because of the poor condition of the mother. In a multipara where it is fairly reasonable to believe that the uterus can be quickly emptied, it is better to induce with pituitrin or manually dilate the cervix, or with Champetier de Ribes bag, and either apply forceps or do a Braxton-Hicks. The action of pituitrin is very fleeting, and I have no hesitancy in giving a full cc. where the emergency is great. I prefer, however, to give five minim doses q. 2 hours until a cc. is given, the whilst giving castor oil or croton oil by mouth if the patient is able to take or by tube if she is not. At the same time a Watkins enema is given, followed by copious proctolysis and a hot pack with ice to the head. In favorable cases Veratrone is employed, but it is a treacherous drug, and is not given if the pulse is faltering any or is even slow and heavy. This fairly conservative treatment can be interrupted at any time for more radical measures.

To revert to the question of Cæsarian section, it must not be forgotten that we have to deal with the situation in hand, but we have also to protect the woman in her future deliveries; and section once practiced does not necessarily inhibit future vaginal deliveries, but it certainly increases their risk. If a section can be reasonably avoided, it should be avoided; but on the other hand, if there is any possibility of its being done, every effort should be made to prevent contamination of the vaginal passages.

So much for antepartum eclampsia. To recapitulate: In the presence of increasing albumen, casts, stupor, diminished urine, positive eye signs and mounting blood pressure, put the patient to bed and stimulate elimination every way possible; if convulsions appear, either control with large doses of morphine, or, in the presence of increasing systolic pressure, empty the uterus by section or forced vaginal delivery.

A much more serious situation is postpartum eclampsia, for the obvious reason that the uterus is already emptied. Phlebotomy, if done, will make for a blood concentration and should not be done without being followed by a replacement of fluid lost, either by intravenous or by proctolysis. Someone has suggested that salt solution should not be used as salt may be absorbed and add to the already present edema and tap water is better. It has also been considered that glucose will stimulate the glycogenic function of the liver, which function is greatly interfered with in eclampsia. I believe that both morphine and veratrum are very depressing and should be used, if at all, with the greatest caution in postpartum eclampsia. The blood pressure should be taken frequently and not be allowed to fall with too marked rapidity, as your patient will surely die from myocardial failure. Strophanthine has been a great comfort to me in the presence of failing myocardium. Uterine contraction should be stimulated by ergot, ice bags and pituitrin in order to see that no membranes or clots are being retained. The bladder should be emptied by catheter at regular intervals for the purpose of study. The main reliance should be on stimulation of the skin by hot packs and of the bowel. Each case should be watched closely and treated empirically. Lumbar puncture, in continued convulsions, is advised.

These fulminant cases of eclampsia are not seen in private practice as they used to be because of the prenatal care that is being given by all doctors. Even in hospital work the dispensaries have done much in the way of prevention. We can never know how many cases might have been eclamptic but for prenatal care.

It is not too much to hope that in time the newer blood chemistry will be able to differentiate between what is primarily renal and what is cardiac in the so-called cardio-renal cases. No one will dispute that eclampsia and uremia are very similar, but it is possible in given cases to differentiate between the two clinically, and certainly at postmortem. For instance, in eclampsia you have a sudden rise of objective symptoms and their subsidence after the removal of the offending cause. In true uremia

the renal disturbance is present long after delivery. At autopsy in uremia you have the swollen capsule of the kidneys with choked glomerulli, but without much change in the liver; whereas, in eclampsia you find the fatty necrosis of the liver with fatty degeneration and edema of the brain. The kidney disturbance in eclampsia is probably secondary. So far, there has not been a great deal of work done on eclampsia, but there has been a great deal of work done on uremia. For one thing in eclampsia, you are faced with a situation demanding immediate conclusions in the vast majority of cases, and it takes time to work out a conclusion from the blood. But as in a case as given below, the case was delivered and a true diagnosis was made subsequently, certainly the blood chemistry was of the greatest value.

In normal pregnancy there has been found a slight nitrogen retention and that the figures for toxemia do not rise much above what is found normally, namely: 40-6 mgs. urea per 100 cc. of blood, which indicates that there is a normal acidosis found in the pregnant state. Moreover, the starvation which is more or less present in any labor case, plus the anesthetic, might be the occasion of any increase of acidosis. The acidity of the blood has been found to be increased in the presence of convulsions and in proportion to the number and severity of the convulsions. The carbon-dioxide combining power is reduced in the presence of toxemia, which also tends toward the acidosis theory; the variations met with, however, are slight. Cholesterol is usually increased and lecithin is diminished. If acetone is found it is of strong diagnostic importance. Clinically, the amount of soda necessary to render the soda alkaline is a slight indication of the systemic acidosis, although, of course, it has little or no effect on the blood, which is necessarily an alkaline fluid. Creatinine increase is of very bad prognosis, also an increase of Ambard's coefficient, both of which signs are of renal insufficiency. It is to date impossible to distinguish between the blood signs of these diseases, and it is extremely desirable to work along these lines in order that more may be learned of the causation of eclampsia, as only in this way is it possible to intelligently hope to do much, either in the way of prevention or cure.

A young woman, age 26, was brought into the hospital with a general and very marked anasarca, not in labor. The urine showed nothing abnormal, and her phenol-sulphone-pthalein test for two hours was 82 percent. She was put to bed on a limited fluid diet, but with no other treatment. The first 24 hours her intake was 1000 cc. and her output was 3000 cc. approximately. First stage pains came on and were borne with a most hysterical attitude. Her anasarca melted away. With the subsidence of her edema she had a convulsion, and her blood pressure, which had been systolic 140 mm. Hg, went to 200 mm. Hg during the convulsion. Her mental state became very torpid, and her urine practically nil. Forceps were applied and a living child withdrawn. The creatinine was only slightly increased, the other blood analyses being negative in their readings. Blood nitrogen was done, Ambard's coefficient found, etc. Had this case gone on she would have been a serious case of true eclampsia, the diagnosis resting on the increased blood pressure, the urine findings, the increase of creatinine, and the absolute torpor; and I believe the condition resulted from the blood concentration, which came about when the edema disappeared.

Another young woman came into the hospital with most violent convulsions following one another in close succession. No urine could be obtained. She gave a history obtained from her husband of intense headaches for the two days preceding the onset of her convulsions. Magnesium sulphate was given by the tube, ether anesthetic was given, a Braxton-Hicks was done, and a dead seven months fetus was withdrawn. Convulsions did not stop and a phlebotomy was done, withdrawing 800 cc. of blood which was replaced by normal salt intravenous. Glucose was given by proctolysis q. 6 hours for several days. Hot packs were given twice. After several weeks the urine still contained a trace of albumen. This patient had retinal hemorrhagic exudates. Her vision at the end of three weeks was impaired. She remained in coma for three days. Her senses were obtunded for some little time, and there are at least two weeks gone out of her life of which she has no recollection at all. This is very characteristic of true eclampsia.

Conclusions. Blood chemistry was done on two supposedly eclamptic cases of mine recently. One case, age 39, a primipara at term, came to my service in the City Hospital. Her pressure, on admission, was 165-90. Her urine had albumen 4 plus, and many granular casts. Her mentality was perfectly clear. She was given castor oil by mouth, and a Watkins enema, followed by a prolonged colon flushing and a hot pack. Under this care her systolic pressure rose to 210, her eye grounds were negative and her urea 226 mg., creatinine 18 mg. per 100 cc. of blood. Although she had no convulsions because she was a primipara and age 39, and because her pressure was high, a Cæsarian section was done and she was delivered of a living child. Had this case been subjected to a slow vaginal delivery, she might have become eclamptic; but certainly, in the absence of convulsions, and in the presence of a perfectly clear mentality, I should hesitate to call her anything more than a potential eclamptic.

On the other hand there was admitted to the hospital a white woman, age 22, who gave a history of scarlet fever in infancy, with nothing intervening until this illness. She had complained of severe headaches the day before entering the hospital, and had seen her doctor, who had examined a specimen of urine and had given her a free purge. She entered the hospital in a deep coma, and all told had ten convulsions. Her blood pressure was never over 160, but her pulse was rapid. No urine was obtained by catheter on her entry. The eye grounds showed both exudates and hemorrhages; creatinine was 1.48 per 100 cc. and urea was 52.4 mg. per 100 cc., the urea being slightly high. Conservative treatment did not influence the progress of the disease and she was dilated with bags, and delivered of a dead child. She did not regain consciousness, and died following a profuse postpartum hemorrhage.

Neither of these cases shows any appreciable alteration in their blood chemistry. I have given pituitrin to eclamptics both to assist in inducing labor and to form contractions following delivery. I always give it with the cuff on the arm, and so far have seen no deleterious results on the blood pressure from its administration. I do not favor the use of veratrum because it is a depressing drug in the first place and in the second place it is aimed not at the cause underlying the high blood pressure, but at the blood pressure itself. Now the blood is one of nature's defenses and little good can be obtained by striking blindly.

Except in extremely grave cases I do not use antepartum phlebotomy. These patients usually bleed at delivery, how much we never know beforehand, so that a previous blood letting may let the defenses down too low. A postpartum venesection is oftentimes of greatest value.

In conclusion: Eclampsia is a condition associated with pregnancy, the importance of which cannot be overestimated. Not much is known at the present time as to the causation of the disease. Early emptying of the uterus in a frocible manner is not always a wise procedure as the patient is not a good surgical risk. The dangers are: death from shock, from hemorrhage and from exhaustion. High blood pressure is not in itself a thing to be feared, as it is in the nature of a protection to the patient. Also high blood pressure by itself is not an indication of impending eclampsia. There are a good many causes of high blood pressure, which may be present without nephritis and many a case of hypertension may go through labor without eclampsia. The conservative treatment is the treatment of choice. Prenatal work will prevent many a case of eclampsia, and this will include careful watching of the urine, the comparison of intake and output of fluid, the phenosulphonthalein test, the regular use of the sphygmomanometer and ophthalmoscope. Rest in bed, purgation and an alkaline diet, at any evidence of nephritis, will enable many a woman to carry her pregnancy to a successful end who might, without observation, have been one of the many victims of this dreadful disease.

DISCUSSION

DR. CHARLES S. BOND (Richmond): I know of nothing which the doctor encounters that is so demoralizing and humiliating as eclampsia. It is so sudden in its onset, it brings terror to everyone in the house, and something must be done immediately to relieve the difficulty. The attacks come on in women close to term, and they are much more frequent in primipara than in multipara. The whole question seems to me to be one of pressure, the placing of the body of the child against returning currents of blood in the mother. Another thing we must think of is that the mother is taking care of the sewage of two persons. She is not alone taking care of her own creatinin and so on, but as the child grows more work must be done, and I think the argument holds good all the way through that it is a question of wastes being thrown into the blood of the mother which she is not able to care for through her avenues of sewage function.

If the mother in infancy has had scarlet fever and has kidneys already blocked to a certain extent, it stands to reason that this mother would have difficulty long before a normal one would. If therefore pressure is the fundamental factor, if it is a gradual filling of the body with waste material that it cannot eliminate, then the argument would be all in favor of getting the cause away as soon as possible. I have had eight cases of eclampsia and the eight women are now living, and if I were called again in such a case I would go back to the same treatment, that is, the delivery of the child, without great haste, but as soon as possible.

Prevention of course is the means to be resorted to in case the patient consult the doctor in time. When albumen occurs in the urine and the feet, hands and face become swollen, the patient should be given liberally of Epsom salts, and from 2 to 10 drops of spirits of glonoin in one-fourth glass of water every two or three hours until the swelling has disappeared. The albumen is of little consequence if not accompanied with general anasarca. If this plan is followed you should have very few cases of eclampsia.

DR. ELMER E. MORGAN* (Fort Wayne): I want to object to the application of forceps in an eclampsia. You can do a podalic version according to the method of Potter and do much less harm than by applying forceps.

*Deceased.

DR. WILLIAM F. SMITH (Huntington): This is a subject that I am much interested in and I wish to compliment the essayist. In 1904 I had five cases of eclampsia, not all my own, and in none of them had I examined the urine. In one case the mother went into convulsions about the time I was called, there was no dilatation whatever, so I did manual dilatation and delivered a breech case. I pushed up the breech and brought the child down and delivered it. This is a very interesting subject to me. In this series of five cases we saved all the mothers but one, and two of the babies were lost. In this one mother the delivery did not seem to help her. She was very toxic. She was delivered about five o'clock and died about six and the convulsions never stopped before death.

DR. CHARLES H. GOOD (Huntington): Of all the tragedies of the lying-in room nothing strikes such terror as eclampsia, and anything we can listen to that will help to prevent this is certainly worthy of fullest consideration. We have had a splendid paper. I have had thirty-six cases of eclampsia in thirty-five years' practice, with twenty-eight recoveries and eight deaths. I think that is an average record. In a paper presented before the American Gynecological Association this year about 30 to 35 percent was the death rate given, and I wish to congratulate Dr. Bond on his experience.

DR. MORRIS H. C. JOHNSON (Vincennes): I would like to ask what experience Dr. Ketcham has had in the dislocation of joints in cases of eclampsia, whether it is usual to examine patients for such dislocation following delivery.

DR. JANE KETCHAM (closing): In response to Dr. Johnson's question, I think there is no danger of dislocation of the shoulders during delivery in using the anesthetic, but I know of cases where a woman has had dislocation following pulling on straps.

In response to Dr. Bond, in regard to types of presentation in eclampsia—I feel that position has nothing to do with the disease. I have had several cases of breech presentation in eclampsia, and one case of twins where both children were breech presentation with eclampsia. This was a very fulminant case. The woman was six-para and had had eclampsia in the last four pregnancies. She came into the hospital in convulsions and had one after another until death occurred after twenty-four hours.

As has been said repeatedly, this is one of the most dramatic situations that ever occurs in any case. The family is always more or less stirred up; they all think the patient is going to die, and when you add to this terrifying disease, the advice to the doctor is to sit tight and not start in to deliver, it is hard on both the family and the doctor. You should try to control the toxemia before you add to the situation the shock of delivery. Very often the shock of delivery is the last straw, and if you can just sit tight until the overwhelming toxemia is controlled, the obstetric risk is improved for both mother and child.

OPERATIVE INJURY OF THE HEPATIC AND COMMON BILE DUCTS

METHODS OF AVOIDANCE AND REPAIR*

H. K. BONN, M.D.
INDIANAPOLIS, INDIANA

Kehr, Rio Branco, Descomps, Ruge, Kunze and Pantaloni have, long ago, described practically every type of anomaly of the bile ducts and of the biliary blood vessels. Recently Eisendrath and Behrend have verified these original observations.

Kehr evidently considers these biliary anomalies of considerable surgical importance, since he devotes many pages in his "Praxis der Gallenwege Chirurgie" to their exposition. In particular he emphasizes these anomalies in their relationship to ectomy and as factors in the production of operative duct injury.

The purposes of this paper are to briefly review the more common anomalies of the biliary ducts and blood vessels, to consider the usual types of duct injuries, to describe the methods of repair of such injuries and finally to define the methods of avoidance of these duct injuries.

TYPES OF CYSTIC DUCTS.—I. The so-called classic type of cystic duct is where an acute angle is formed by the union of the cystic and hepatic ducts, and this type is found in 75 percent of cases.

II. The parallel type of duct is that form in which the cystic duct parallels the hepatic for some distance before uniting with it. This parallel type is divided into two varieties: the short parallel variety is where the duct unites with the hepatic duct before the upper surface of the duodenum is reached and occurs in 5 percent of cases. The long parallel variety of cystic duct occurs in 12 percent of cases and is that variety where the cystic duct unites with the hepatic beneath the duodenum.

III. The spiral variety of cystic duct is that type wherein the duct either crosses on top of the hepatic duct or winds beneath it, to enter the left aspect of the hepatic duct; spiral cystic ducts are found in 8 percent of cases.

In the preceding, I have used Eisendrath's percentages since he has studied a large number of cadavers and, by first injecting the ducts with warm bismuth paste and then radiographing them, he has secured a greater degree of accuracy.

(*) Presented with lantern slide demonstration before the Section on Surgery, Indiana State Medical Association, Indianapolis session, September, 1921.

ANOMALIES OF THE HEPATIC DUCTS.—The anomalies of the hepatic ducts are as follows: An accessory hepatic duct may, (a) empty into the right hepatic; or (b) into the main hepatic; or (c) empty into the angle of junction of the cystic and main hepatic ducts; or (d) may empty into the cystic duct. The right hepatic duct may empty into the cystic duct or vice versa.

Other unusual anomalies of the biliary duct system are, a double common duct with a communication between the cystic and main hepatic ducts, or, two accessory hepatic ducts emptying into the gall bladder. (Kehr's cases.)

ANOMALIES OF THE BILIARY BLOOD VESSELS.—In one-third of all cases, the cystic artery has its origin from the common hepatic and not from the right hepatic branch of the hepatic artery. Under such circumstances, the cystic artery crosses on top of the hepatic duct. In 12 percent of cases, two cystic arteries are present, both of which do not necessarily come from the right hepatic branch of the common hepatic artery. Not infrequently, an anomalous artery may originate from the gastro-duodenalis, and run upwards in an oblique direction to the gall-bladder, crossing the common duct in its course. This vessel may be the cystic artery or may be an accessory vessel.

THE VARYING RELATIONSHIPS OF THE HEPATIC DUCT AND ARTERY, THE PORTAL VEIN AND THE COMMON DUCT.—The interval separating the hepatic duct and artery varies from immediate apposition to 25 mm. Not infrequently one overlaps the other. The multiplicity of possible deviations from the supposed normal are so numerous that sufficient space for their description cannot be given in such a limited paper as this.

CLASSIFICATION OF OPERATIVE DUCT INJURIES.—These injuries are here classified as to their time of occurrence, *i. e.*, whether recognized at the time of their production or later. Here I again quote Eisendrath as his is a practical working classification. He has collected 51 cases of duct injuries, due, he states, either to errors in technique or to anatomical variations of the structures concerned.

Eisendrath has classified duct injuries in four groups:

I. Those cases in which the injury was recognized at the time of operation, or shortly thereafter, and immediate repair instituted. This group affords the majority of cases reported—26.

II. Those cases, four in Eisendrath's report, in which an immediate or early repair of the injury was not successful, necessitating a secondary operation.

III. In fourteen cases, the injury was overlooked at the time of the primary operation, a secondary attempt only at repair being made, and this usually for stricture.

IV. Miscellaneous cases; exemplified by such cases as that of Delageniere, quoted by Kehr, wherein accidental division of the ducts, during ectomy, was followed by recovery, or as in two cases of Moynihan's, where the ducts were divided, a split tube inserted and recovery ensued. A further example of this miscellaneous group is the case of Lilienthal, wherein the hepatic duct was ligated, the accident going unnoticed until icterus developed. This patient died.

MODES OF DUCT INJURY.—I. Tear or resection of one or all of the ducts may occur at the site of union, one with another. Undue traction on the gall bladder during ectomy or the placing of a forceps, somewhat blindly on the cystic duct, as in the instance of a large empyema of the gall bladder where it is not desirable to aspirate first, are factors in the production of this type of duct injury. Likewise, the presence of anomalous or multiple blood vessels, wherein vicious hemorrhage ensues from an unexpected source for one reason or another, resulting in hasty and blind but ill-advised attempts at control of such bleeding, make for duct injuries.

II. Tear, division or ligation of the main hepatic or common ducts during separation of the ampulla of the gall-bladder or the stripping free of an adherent parallel cystic duct, can occur. Complete division of the common duct where a spiral cystic duct obtains, may occur, as where a clamp has been applied for any one of several reasons, at right angles to the duct.

III. The common duct may be torn, divided or ligated, due to efforts to control bleeding coming from the depths of the operative field, or the duct may be split in the removal of a stone, which is tightly wedged. A scallop from the wall of the duct may be removed by the application of a clamp to the terminal end of the cystic duct, by making the application too close to the common duct. Efforts to grasp the spurting end of an anomalous artery, originating from the gastro-duodenalis and coursing upwards to the gall-bladder, may result in crushing or ligaturing the duct.

IV. Various anomalies of the ducts being possible and fairly common, it is not particularly difficult to divide or ligate any one of the ducts if due care is not exercised.

METHODS OF REPAIR.—I. The so-called ideal methods of repair are usually not applicable except in recent cases. A. Circular suture, somewhat after the technique of Carrell's blood vessel suture, is perhaps the best procedure. B. A rubber tube may be utilized in circular suture in several ways, thus: there may be made an end-to-end anastomosis of the common duct over the tube, which is allowed to emerge either thru a separate opening in the duct or thru the ampulla of Vater (traversing the entire length

of the common duct). Again, the transduodenal method of Voelcker or Hoerz, wherein an end-to-end anastomosis of the duct is made over a rubber tube which is allowed to emerge thru a separate opening in the duodenum, may be found useful.

II. Incomplete repair may be made by incomplete circular suture, in which the T-tube of Kehr or a plain rubber tube (passed onward thru the ampulla of Vater), may be utilized. In this type of repair, only the posterior wall of the duct can be sutured and a cuff of omentum may be applied at the site of suture for further security.

III. Hepatico-duodenostomy after the technique of Witzel, Coffey or W. J. Mayo may be found to be applicable in some instances.

IV. A flap from the stomach, colon, or cystic duct or gall-bladder (if available) might be employed to bridge the gap in the walls of the duct. This has been done successfully by Kehr.

METHODS OF AVOIDANCE OF DUCT INJURIES.—The special factors of safety are:

I. Knowledge of possible vessel and duct anomalies.

II. Methods of control of unexpected and alarming hemorrhage: (a) finger compression of Pantoloni, by utilizing the forefinger in and beneath the gastro-hepatic omentum, the thumb being applied on top of this structure; (b) avoidance of hasty blind clamping; (c) feeling the vessel spurt against the finger and applying a clamp only after quick sponging of the site of bleeding to clean the field, under direct vision of the bleeding vessel.

III. Aspiration, by means of a fine hypodermic needle and syringe, of any structure, if in doubt as to its identity, *i. e.*, whether portal vein, hepatic artery or the duct.

IV. Ligate or clamp all strands of suspicious tissues (referring here more particularly to anomalous vessels) doubly before dividing.

GENERAL FACTORS OF SAFETY.—I. Ample incisions should be employed so that adequate exposure of the operative field is obtained. Kehr's Bogenschnitt and Wellenschnitt are useful incisions; likewise Bevan's hockey stick incision, supplemented by an additional angulation to the right at the lower end serves well frequently.

II. Proper placing of sponges is important. When possible, a sponge should be placed beneath the foramen of Winslow so as to elevate the structures contained in the gastro-hepatic fold. Masson's method of producing elevation of the liver by the insertion of a sponge pack between the upper surface of the liver and the diaphragm may be found useful. I have no experience with this procedure.

III. Proper delivery of the liver by traction after the plan of Mayo-Robson is of great importance.

IV. Behrend considers the opening of the anterior leaf of the hepato-duodenal ligament and the identification of the supra-duodenal portion of the common duct to be the most cogent factor of safety.

V. The separation of the ampulla of the gall-bladder from the common duct should be done with the utmost caution, followed by the identification and exposure of the cystic, hepatic and common ducts and the cystic artery. Due consideration for the possible anomalies of ducts and blood vessels should be made. The cystic artery should be ligated preferably close to the neck of the gall-bladder and complete isolation of cystic duct and artery should be carried out before such ligation is done, if at all possible.

VI. All other factors being equal, if the common duct is to be opened, the site of election is the supra-duodenal portion.

VII. At all stages of an ectomy or a choledochotomy, it is well to keep in mind the possibilty of an anomaly of either the gall-bladder, the gall ducts or of the biliary blood vessels, being present.

DISCUSSION

DR. H. O. SHAFER (Rochester, Indiana): In removing the gall bladder I dissect it, sometimes split it, and go down to the cystic duct; but I think if we remove all of the cystic duct we may do more harm than if we leave a portion. My experience over quite a few years has not made me want to change that technique. I feel the patient is in better shape and there is less damage done in the abdomen. The ease with which it is done is so much more apparent to me than to clamp off the cystic duct and work up.

One of the things that has worried me in surgery of the badly infected gall bladder is the infection we may get that goes to the liver or the pleura. I have had cases of empyema of the gall bladder which resulted in empyema of the chest by direct continuity.

As to the closure of the wound, I do not think that is the thing to do. I think the cigarette drain naturally takes care of that. I believe also that when we remove a stone from the common duct the best thing is to put in a small tube down to the common duct with a couple of cigarette drains, and these cases get well. Nature does wonderful things toward relieving that bile in the normal way, and if we do not completely sever the common duct nature will take care of it. It seems to me that drainage there is safer than any operative procedure we might do. Further, I might say that I believe in our gall bladder cases, taking them as they come, year in and year out, our mortality is higher than in any other cases. Within the last year I had four ruptured gall bladder cases in the hospital at one time. I do not suppose it will ever happen to me again. In three of

these cases I removed the gall bladder completely. In the fourth with only drainage, gangrene had set in and the patient died from extensive necrosis.

I believe in these cases we must take care of our patients first—remembering that anomalies may get us into trouble, but always playing safe, draining and letting nature do the things which she is always so kindly doing for us.

DR. GOETHE LINK (Indianapolis): In my experience more than fifteen percent of all gall bladder and bile duct cases have required operation upon the common duct; but every one of these cases had, at one time, been strictly a gall bladder case. Therefore, in dealing with a large percentage of common duct cases I was dealing with neglected pathology. There are a number of reasons for this, but let us pass them by saying that we do not operate our gall bladder cases early enough.

A surgeon should bear in mind that fifteen percent of these cases of gall bladder surgery are common duct cases and he should go further in his surgery than some of us have been going. He should explore the common duct more often. It has been definitely demonstrated that frequently we cannot palpate stones in the common duct when they are present. If the common duct is dilated, if there has been jaundice, if there has been leukocytosis and high temperature, the common duct should be opened and explored, and in order to do that we should have knowledge of the very anatomy that Doctor Bonn has shown us so nicely.

The common duct should not only be explored more often, but it should be treated by drainage; the drainage Doctor Shafer insists upon should extend to the common duct. The sphincter of Oddi should be dilated and a T-tube fastened in the common duct. We should have more surgery done in this region which Doctor Bonn has so well elucidated.

DR. B. VAN SWERINGEN (Fort Wayne): I want to take issue with this statement about drainage of the common duct. From an educational standpoint I do not see why anybody wants to drain the common duct. If the operation has been done properly, the common duct will have been cleared of all stones that are in it and drainage through the duct will have been instituted. Then the way is clear for anything in the common duct to be carried along with the bile as it makes its escape into the bowel. To my mind T-tube drainage of the common duct is absolutely worse than useless. It keeps up the nausea after operation, provokes vomiting as long as the T-tube is in there, and also gives rise to considerable distress which amounts to actual pain.

I am not averse, however, to drainage; but not drainage of this duct. I think that is absolutely contraindicated. A tube or drain surrounded by gauze laid in the bed of the gall bladder and down to the common duct is all that is indicated, and that is all that is necessary to insure perfect apposition and closure of the peritoneum covering the gall bladder.

DR. JAMES J. MOOREHEAD (Terre Haute): A few years ago in Chicago, while engaged in research work regarding the duodenum—to determine whether this portion of the gastro-intestinal canal is essential to life—I inspected carefully the biliary tract in a large number of the dogs used in the work. Anatomical anomalies such as have been so well described by Dr. Bonn were occasionally noted.

A complete duodenectomy required transplanting the common bile duct into the jejunum. Following considerable experimentation with other methods we adopted this simple procedure: A jejunal opening was made of just sufficient size to permit the duct to be drawn into the lumen of the bowel by a thread armed with two needles; this tractor was tied 2.5 cm. distally; one sero-serous suture effected closure around the duct. The pancreatic duct was likewise transplanted.

DR. ERNEST I. BRENNER (Winchester): Just one question in regard to the drainage of the common duct. In these cases of common duct involvement we always have a cholangeitis. That means that we have inflammation, and if we have inflammation we must have some obstruction at the ampulla. If that is so, if we do not put drainage into the common duct the inflammation will close off our opening and we defeat our end in that we do not get "free" drainage.

DR. A. S. JAEGER (Indianapolis): We know the question of how best to deal surgically with gall bladder diseases has been under discussion for a long time and probably will be until as long as each surgeon has his individual method of doing his work. The question of whether one should drain the common duct depends on the individual case upon which one is working. Doctor Link favors draining the common duct. So do I, but I know he will admit there are cases he does not so drain because it is not indicated. But I believe everyone will admit that it is not very good to close the abdomen without some form of drainage, whether directly into the common duct or not.

Just so long as most of us refuse to admit that we may have gall stones which do not originate within the gall bladder we will have trouble. Just so long will they operate such cases, the patient recovering nicely from the operation and then coming back after a while complaining of the original trouble. His biliary tract has not been properly drained, for the infection in the bladder is the result of a condition which originated outside the gall bladder, and the effect has been removed but not the cause. Consequently there is sooner or later a recrudescence of the primary pathology.

DR. H. K. BONN (closing): Dr. Van Sweringen says that pain and distress is always present when a T-tube has been used. Yet Deaver reports a patient who has worn a T-tube for three years without discomfort.

I cannot see how a common duct, from which stones and debris have been removed, can be expected to carry bile into the duodenum when we consider that this same common duct must have been somewhat irritated in removing the stones, and that inflammatory changes of some degree will occur, which may block the duct temporarily. It appears to me that a T-tube, properly placed, will carry away the bile and afford the common duct the necessary rest to permit the inflammation to subside. Dr. Link has stated my position exactly in regard to common duct drainage.

In order not to leave a wrong impression, permit me to state that I believe in T-tube common duct drainage whenever indicated. I do not believe in closing the abdomen without drainage after simple cholecystostomy but prefer using a cigarette drain to the stump of the cystic duct as a factor of safety.

LUDWIG'S ANGINA*

WILLIAM F. MOLT, M.D.
INDIANAPOLIS, INDIANA

In presenting this subject I make no pretense of having anything original, but wish to review very briefly what has been said in the past about this very grave and often fatal disease, and to report a case which began in a very unusual manner.

We as otolaryngologists should be more familiar with the diseases and anatomical relations of the head and neck and thereby better fitted to treat this disease intelligently.

In Dan McKensie's recent work, *Diseases of the Nose, Throat and Ear,* we learn that "septicemic pharyno-tonsilitis, variously known as gangrenous sore throat, acute cellulitis, acute edema of the pharynx, and perhaps most generally as Ludwig's Angina, is a rare and peculiarly virulent, often fatal, affection of the throat and cervical cellular tissue, characterized by intense and widespread local inflammation, and by profound and often rapidly fatal toxemia.

"It is a form of septic cellulitis or erysipelas of the submaxillary region and neck, secondary to a streptococcic or pneumococcic glossitis. It is characterized by the formation of a hard, brawny swelling of the parts under the jaw, and in the upper cervical region. The floor of the mouth, the fauces, the pharynx, and the larynx participate in the general phlegmonous swelling, and severe constitutional disturbances co-exist. There is grave danger of life from septicemia, from edema of the glottis, and later from exhaustion."

Other English and Continental writers have given us information concerning this condition, with numerous case reports, but in this country comparatively little attention has been paid to it, at least if one may judge from the paucity of the literature. Many text-books by American authors do not even mention it, and during the past ten years only a few scattered case reports have been made public.

There also exists a good deal of confusion in regard to the name itself. Newcomb remarks that it is always unfortunate to attach the name of an individual to a pathological process, for while it may at first serve for more ready identification of the condition, subsequent study is almost certain to modify its clinical significance; and because the name gives neither anatomical nor pathological clew it can easily become both misleading and confusing. In this particular case, the title is unusually inappropriate, for Ludwig of Stuttgart, after whom it was named, was not really the first to publish an account of it. His observations appeared in 1836, but there is a record which leaves no doubt that the condition had been definitely described long before Ludwig's time.

In 1822, Dr. George Gregory published in London an account of the illness, death and post-mortem of one Ann Jones, housemaid, aged 25, who presented, on admission to the hospital, "pains in the neck, with fever and great difficulty in swallowing, swelling and tenderness all about the neck, but especially at the junction of the clavicles with the sternum, from which no essential relief was obtaind by bleeding or purging." The disease progressed rapidly, breathing became so impeded that the tongue assumed a "blue colour", and "to relieve this, blood was twice drawn from the arm, but the alleviation was very momentary". Despite the continued bleeding, the patient managed to survive seven days. When the autopsy was performed, it was found that "the cellular membrane beneath the skin of the throat and around the trachea was everywhere in a state of disease, and the same disorganized condition of the membrane pervaded the whole extent of the anterior mediastinum, even as low as the point of the fusiform cartilage." To this singular variety of quinsy, "Dr. Gregory ventures to apply the term *cynanche cellularis,* from a belief that it has not yet received any more appropriate appellation".

This article makes reference to three earlier writers, Mr. James, of Exeter, in his work on *Inflammation* (p. 188), Dr. Kirkland, in his *Enquiry into the Present State of Medical Surgery* (Vol. 2, p. 159), and Dr. Wells, whose "case of extensive gangrene of the cellular membrane between the muscles and skin of the neck and chest" which he reported to the Society for

*Read before the Section on Ophthalmology and Otolaryngology of the Indiana State Medical Association at the Indianapolis session, September, 1921.

the Improvement of Medical and Chirurgical Knowledge on May 2, 1809. This seems to be the first description of this condition ever published. In his account Dr. Wells informs us that the patient's illness began by her feeling "a pain in her bosom and collarbones and being often chilly. These ailments were attributed to her staying much in a room the doors and windows of which were frequently open". Then "the left cheek began to be painful, red and swollen. This disease of the cheek was at first thought to arise from a bad tooth, but as it increased quickly, an apothecary was sent for. The swelling and redness * * * had now reached the left clavicle and * * * the apothecary conceived that those symptoms depended upon an inflammation of the parotid gland".

Dr. Wells, called in consultation by the "apothecary", was unable to relieve the patient, and she died on the third day after his first visit. After much "reluctance" he gained permission to make a post-mortem examination. "When an incision was made through the skin of the thorax, a very fetid liquor of a dark brown color flowed out, the quantity of which * * * was estimated to exceed half a pint. Upon turning the skin aside, a most hideous sight presented itself, the whole cellular membrane, which covered the muscles upon the fore part and sides of the neck and chest, being discovered to be in a state of gangrene".

The description of these early cases is not very different from the most recently published clinical records. R. W. Parker, in 1879, published an extensive historical resume of what had been writen concerning cellulitis of the neck, or "angina Ludovici" up to his time, and sixteen years later, James E. Newcomb read a paper before the American Laryngological Association, which contained additional collected cases. But during the past twenty-five years, despite the great advance made in all branches of otology and laryngology the literature concerning the condition is very scanty. The most recent authoritative pronouncement regarding it seems to be that of Dr. Halphen who, in 1918, had this to say to the surgeons of the Fourth French Army:

True Ludwig's Angina, very rare, is characterized by the gravity of the general symptoms, the patient being prostrated almost before the pus collection has had time to form. Ludwig's Angina, improper designation (*mauvaise denomination*) of an affection discovered by Gensoul, five years before Ludwig, can be called an angina only because of the extreme anguish of the final period. It is really a hypertoxic form of gangrenous phlegmon of the floor of the mouth, similar in form to a massive gangrene in the course of severe wounds of the limbs, or like that of a suppurative appendicitis. Ludwig defined the condition as a "gangrenous induration of the neck" and enumerated the diagnostic features in this way:

(1) Slight inflammation of the throat itself which even when it is present disappears after a day or two, and which when it persists may be looked upon as of secondary diagnostic importance; (2) a peculiar "wood-like" condition of the connective tissue, which does not pit on pressure; (3) a hard swelling under the tongue, with a bolster-like swelling around the interior of the lower jaw, of a deep red or bluish-red color; (4) a uniform spread of this induration in such a way that it is always sharply bordered by a zone of entirely unaffected cellular tissue; (5) escape of the glands, although the disease attacks their cellular-tissue surroundings and may even commence therein.

It is noticeable that all subsequent writers agree with Ludwig in the first four features, but that there is much difference of opinion in regard to the fifth.

A modern definition from the clinical side is given by Gerster, an American writer: "A phlegmonous destruction of the submaxillary gland, characterized by alarming and extensive dense edema, caused by the unyielding character of the fascial envelope of the gland; which edema is most manifest about the latter's vicinity, *i. e.*, occupies the floor of the mouth". It will be noticed that most of the modern definitions limit the inflammatory focus to the submaxillary gland, while the earlier ones include a much more extensive area.

Thomas (Annals of Surgery 1908) in a very exhaustive article says the location of the submaxillary gland between the posterior border of the mylohyoid and the middle constrictor muscles is responsible for the rapid development of the edema of the glottis in Ludwig's angina, and that the infection is usually due to the streptococcus.

It is noticeable in examining the various case reports, how often the history contains reference to various dental difficulties, which *at first* were thought to be the cause of the cellulitis. Many of the victims were young people between twenty and twenty-five, in whom the eruption of the posterior molars may have been suppressed or have given rise to infection for other reasons. Yet Hamann, writing in 1899, appears to be among the first to state that he believed cervical suppuration to be generally due to such a cause. "*Dental and peridental affections are the most common causes of extensive submaxillary suppurations. Any septic process in the mouth, however, is likely to be followed by lymphatic and glandular abscess.* In one of the severest cases I have ever seen, the infection began in the tonsil. Scarlatinal and diphtheric inflammations may lead to the most serious cervical abscesses, which are at times associated

with sloughing and gangrene. It is probably cases of this sort that Ludwig saw when he first described the disease."

As the glands in the submaxillary region receive the lymph from the oral cavity, they are generally the ones primarily affected. The deep cervical fascia have an important influence in determining the course of abscesses and in directing the spread and extension of inflammatory products; but more than the fascial layers themselves, the spaces or intervals between the various organs of the neck, where the connective tissue is rather lax, allowing mobility of the parts, permit the inflammatory process to extend and the pus to infiltrate the tissue.

The submaxillary gland is enclosed in a rather firm fascial covering, from which fibrous bands extend in various directions. Around it, however, there is considerable loose, connective tissue. When inflammation of the submaxillary gland, or of the lymph glands contained within its fascial investment, occurs, there will be tension on the capsule, and a marked collateral edema of the surrounding parts. As dense tissue surrounds the infected area, the likelihood of sloughing and gangrene is very great while the swelling and inflammatory induration of the tissues may lead to compression of the respiratory passages and edema of the loose, submucous tissue. So, even if the process begins in the submaxillary region, it is practically certain to extend, sometimes as far as the opposite side of the neck.

The previsceral space of Henke lies between the trachea, larynx and thyroid gland, and the ribbon-like muscle in front of them: if an abscess forms here, it may exert pressure upon the air passages and extend into the anterior mediastium. There is a third connective tissue space around the great blood vessels of the neck, upon which lie the deep, cervical lymph glands. An abscess located here will raise the sterno-mastoid muscle, gather between this muscle and the trachea, or possibly descend into the mediastium. Postpharyngeal abscesses may occur in the retrovisceral space behind the esophagus and pharynx;—and, there is still another space at the lower end of the sternomastoid, posterior to which are the great vessels of the neck and the scalene muscles and from which there is communication with the axilla, as well as the space about the carotid artery and jugular vein.

Newcomb describes the symptoms as both constitutional—either sthenic or asthenic type—and local, presenting the following diagnostic points:

(1) A wooden-like induration of the affected region, sharply defined from the surrounding normal tissue; (2) the thrusting forward and upward (by the accumulating inflammatory products) of the tongue toward the palatial vault; (3) severe dyspnea with the attendant danger of laryngeal edema; (4) the presence of a hard pad or button-like swelling at the internal aspect of the dental arcade. All of these occur with general pain, redness, heat and swelling of the cervical region; "that is", the classic symptoms of a phlegmon. Swallowing is painful, if not impossible. Usually, the mouth can hardly be opened, as the muscles performing this function are partly imbedded in the infiltrated cellular tissue and partly participate in the inflammation. This is especially true of the mylohyoid, which, being the muscular floor of the mouth, is raised in deglutition.

The prognosis is grave. Newcomb (1895) gives a mortality of 43 percent. More modern surgical methods and earlier diagnosis have somewhat reduced these figures, but even today the outcome is very often fatal.

Early, free and deep incision, rigid antisepsis and general supportive treatment offer the only chance of cure. Gerster says emphatically, "In angina Ludovici, there is great necessity of early and ample incision. The object is not so much to evacuate pus as to relieve tension." He regards the submaxillary gland as the focus of mischief, and attaches a practically pathognomonic importance to the fact that pressure over the edematous area rarely elicits pain except directly over the gland. Even if the patient is unconscious, such pressure will cause unmistakable signs of distress, and if these appear, there is no excuse for delay. "There being no 'pointing' as in an ordinary abscess; therefore, we must first expose the entire area of the gland. In a typical case, the gland will be found more or less disintegrated, and inside its original connective envelope is ichorous fluid or thin, offensive pus."

There is a form of cellulitis of the floor of the mouth which affects the sublingual region only, which is usually of dental origin. This type of infection may be drained by a free sublingual incision, and oftentimes such cases, if only slight, recover spontaneously. But these are in no sense typical Ludwig angina, as previously described.

A case of this type came under my observation, referred to me by Dr. N. E. Harold. Mr. R., age 39 years, had a molar tooth extracted, which was followed in 24 hours by a swelling in the floor of the mouth, considerable pain, difficulty in swallowing and some obstruction to breathing, the last due to swelling and elevation of the tongue, and upward pressure of the floor of the mouth.

There was no involvement of the submaxillary region. The induration was localized to the sublingual region only and did not at any time extend farther. The patient was sent to the Deaconness Hospital, a free sublingual incision was made under local anesthesia, releasing a moderate amount of pus. On account of

the edematous condition of the sublingual mucosa, drainage was not satisfactory; yet, after two weeks of streptococcic delirium, the patient recovered.

This case would have recovered much more safely and quickly had the incision been made externally through the mylohyoid muscle.

It should be borne in mind that general anesthesia is not safe in such cases, unless one is prepared to do a hurried tracheotomy. Local anesthesia should always be used if possible, and best used with scopolamine and morphine.

The case I wish to report differed from the usual in that the parotid gland was the first to become involved, and from the findings on the first examination (which were a slight ulceration on the gums and the mouth of Steno's duct, and a clearly negative pharynx), led me to believe that the infection in this case extended through the parotid duct to the parotid gland, thence spreading downward, and forward, through the lymphatic channels.

CASE REPORT—Mrs. W. S. H., age 62 years. Family history—Neg. Personal history—No illness since childhood.

On May 23, 1920, the patient complained of a soreness on the inner side of right cheek in the region of the upper first molar, which she attributed to an ulceration she had had on the gums. Two days later she noticed a hard swelling in the parotid region, which rapidly grew worse. About eight hours after the parotid swelling began, I saw the case with Dr. N. E. Harold.

We found a marked board-like swelling of the parotid region, the right cheek, and the submaxillary region—the temperature 102, pulse, 118, respiration 22. Within eight hours the swelling had extended to the floor of the mouth, and almost to the clavical on the same side. The mouth could not be opened, and the tongue was pressing upwards tightly against the teeth. The pressure on the pharynx together with an edema of the glottis was causing very great difficulty in breathing. A diagnosis of Ludwig's Angina was made, and immediate operation advised. Sixteen hours after beginning of the parotid swelling, we operated on her under morphine and scopolamine, ether anesthesia, at the City Hospital as a private patient. A deep incision was made from the lower border of the parotid gland downward and forward, down to and through the deep facia, to the median line, cutting the anterior belly of the digastric, partly exposing the larger vessels, the submaxillary glands, and the submaxillary lymph nodes. Connecting this incision with a deep incision upwards through the full length of the mylohyoid muscle which opened the floor of the mouth and exposed the sublingual glands. The glands were opened and a moderate amount of cheesy purulent material was released. The pressure on the floor of the mouth and larynx was immediately relieved, and breathing became easy. The wound was left open, and dressed with moist boric acid gauze, which was changed every four hours for the first few days. Strych. gr. 1/40 was given every four hours, together with other supportive treatment, under the direction of Dr. N. E. Harold.

The temperature following the operation ranged between 98.6 and 99.8 and after three weeks the patient left the hospital. The wound was entirely healed in five weeks.

There was an interesting feature about the parotid gland in this case, as it sloughed out so completely within five days that the facial nerve could be plainly seen, lying free in the wound.

There was a question as to local or general anesthetic in this case, but with the enormous swelling and extensive incision contemplated, we decided in favor of morphine, scopolomine and ether. We were prepared, however, to tracheotomize at any moment, but such was not necessary.

I have seen within the last few years in consultation two other cases of Ludwig's Angina, both resulting fatally, which I mention only to emphasize what has been said in regard to early and free incision. In one of these cases the incision was insufficient, due to a faulty local anesthesia. And in the other, incision was done under general anesthesia, was free enough but was done too late, I think four days after the onset.

DISCUSSION

DR. HARRY BOYD-SNEE (South Bend): I recall a case which developed Ludwig's angina as a complication in the course of an acute suppurative streptococcic epiglotitis. The initial primary infection made its appearance as an unilateral inflammatory reaction presenting submucosal edematous infiltration which was definitely limited to the right side of the epiglottis. Within a few hours a destructive superficial ulcerative process supervened which was followed by extension of the infection into the sublingual region manifesting itself clinically as a typical Ludwig's angina. The complication

was treated surgically through an incision similar to that described by the essayist. In spite of the operation performed the disease progressed to a general involvement of the deep structures in the neck on the right side extending into the mediastinal region which condition necessitated a secondary operation. This case came to a fatal termination through general sepsis.

DR. DAVID F. BERRY (Indianapolis): My personal experience is limited to two cases of pseudo-angina. Both recovered without surgery.

I wish to accentuate the necessity for an early diagnosis. If dealing with a genuine Ludwig, insist on immediate operation. Boldness, but not recklessness, in operation. This is no field for timidity. The patient's life depends on thorough drainage established early, with a minimum of shock.

I believe the knife less objectionable than the Pacquelin cautery, as advocated by some able surgeons, for incising the swollen tissues. The cautery destroys tissue far beyond the line of incision and as there is usually extensive destruction of tissue from the infective process, it seems more fitting to avoid adding a complication.

I have personally known of two cases operated under general anesthesia, both resulting fatally. I believe the unhappy results were facilitated by general anesthesia. Local anesthesia is greatly to be preferred.

Henri Aboulker, of Algiers, reports ten cases of genuine Ludwig, five of which he operated under general anesthesia with four deaths. Five cases operated with local anesthesia, all recovered. He advocates the use of 1-200 sol. of novocaine, 1 minim of 1-1000 sol. of adrenalin to each c.c. colored with methylene blue. This enables the surgeon to see, as he dissects, if his infiltration of tissues has been adequate to control pain.

PHYSICAL INEQUALITY OF SCHOOL CHILDREN*

G. W. SPOHN, M.D.
ELKHART, INDIANA

There is a great difference in the intellectual advancement of school children. Some are naturally bright because of their inheritance and favorable opportunities; others in the same grade progress slowly under adverse conditions. The advancement of the backward children is hindered, in many cases, by correctable causes. The love of study may even be destroyed under the load of physical imperfections. Before the school year begins in the autumn parents of backward children seek the advice of physicians with the hope that their children will advance as rapidly as any in that grade.

There is a close union between parents and their children; whether it is due to associations, to blood ties or to love is a mooted question. The origin of the family feeling is not of much importance as long as both parents and children recognize the relationship, and are dutiful to each other and the state.

Because of their age and previous experiences, parents have a better knowledge than their children of the needs and preparations to meet the battles of life. The correction of physical defects should not be left optional with children. If the young are determined to rule in matters that are detrimental to their future good, they must abide by the consequences, which is very much opposed to the wishes of the parents.

Families are associated very closely and intimately with physicians. All the physical and mental ills are told to the family physician. Much of a physician's work is a mystery to the laity. The lack of human anatomy and physiology may be the reason why so many seek the opinion of those who are familiar with the subjects. This great confidence is an honor and a responsibility that should be appreciated by all members of the profession. To be worthy of this great confidence a physician should always be honest with his clientele, and live the open and honest life of the "Meek and Lowly One".

Parents have a natural interest in the progress of their children. They may even shield them in wrong because of the family pride and parental love. If blind to the errors of their children, the court accomplishes most when the judge administers the mantle of charity instead of the iron rule of censure.

In children who are mentally defective, mothers do not generally recognize the lack of mentality until it is pointed out to them. Normal or slightly abnormal children look and act the same until they are from two to five years old. Cases of myxedema or imbeciles may show their mental defectiveness earlier. Parental devotion is real; the great motherly love of which poets sing is normal. The same is true in the lower animals; many a mother will defend her offspring against enemies rather than save her own life.

To recognize the love and intense interest that parents have for their children is to acknowledge the ideals and desires that parents want their children physically fit when they enter school. Teachers and officers of the law tell us that children who are physically normal do better work and are more obedient than those who are physically defective. Many children are outdistanced in school work by their inferiors because of some physical hindrance that could be corrected easily. Children are born with

(*) Read before the Section on Medicine of the Indiana State Medical Association at the Indianapolis session, September, 1921.

different abilities; the laws of eugenics are uncontrollable, but descent is not the only consideration. I acknowledge that inheritance is the power that can drive the world, and that all stock can be improved by correct breeding, but this paper refers only to physical unfitness, to acquired imperfections, and not to inheritance. As good blood may become impoverished by avoidable infections, so good qualities may be submerged by physical unfitness.

An educational propaganda along the line of physical inequalities has been carried on by lectures, magazine articles and the daily papers. There is no real law or ethics that opposes such movements, yet there is a so-called "gentleman's law" that frowns upon anything along the line of medical education to the laity. It is unethical to entertain anything along the line of quackery, and perhaps the medical profession considers all educational propaganda by the various magazines and dailies as quackery. We, as a profession, may be right in our opposition, but the changes that have taken place in the attitude of the public would indicate that we are losing ground. The tide of professional opposition has been battered down by the advocates of better hygienic surroundings and better manhood. It is evident that the opposition cannot stop the propaganda of better children, better mothers and better men.

There are enthusiasts *in* and *out* of the profession. How much and what to teach the laity is an unsettled question. Ten years ago no one would have attempted to teach sex hygiene in our public schools, yet it is being practiced today; and besides, the laity is being taught many other things that may be detrimental in the future. The opposition may allude to acts of indiscretion due to the educational propaganda; but even this may be displaced by *good*, which generally predominates. Statistics ten years hence will tell whether the state has progressed or retrograded.

In 1900, before the Indiana State Medical Association, I read a paper on "The Evils of Mouth-Breathing". In that paper I stated that about 30 percent of the population breathed through the mouth, and that *man* was the only animal that had acquired the habit. It was also shown that mouth-breathing caused many disagreeable symptoms and pathologies, such as lack of proper aeration of the blood, causing anemia; interference with natural drainage of the sinuses of the nose and ears; interference with the recovery of all continued fevers, as typhoid, pneumonia, etc.; and most sore throats. The conditions have improved very much, but there are still a few correctable causes.

The class with deformed jaws and nose baffle the skill of surgeons and dentists. The condition was caused by inheritance followed with mouth-breathing. Many of these cases can be avoided by following the advice of the welfare stations and teaching parents that it is possible to educate away from inheritance, if begun early. Thus, in the distant future, there can be no nasal or oral deformities because the mouth and nose will be ideal. Twenty-five years ago, parents, teachers and many physicians believed that nasal respiration was not essential to good health. At that time from one-fourth to three-fourths of the pupils in each school room were afflicted with some physical defect that might have been corrected, if the family physician had given his consent. Hence, the educational propaganda that has been going on without the assistance of the family physician. Physicians, teachers and parents agree that pupils should be physically fit for school work and that all pupils should be given an opportunity for mental as well as physical development.

It is supposed that those in charge of welfare stations, and physicians in general, have the ability to tell the intellectual status of all children brought to them. It is not right nor honorable to make parents believe that their offspring is normal when they are mental defectives. The time, energy and money spent upon morons is wasted. Limitation of time in this paper will not allow even a suggestion, or remedy. Most errors by parents or teachers are made through ignorance of the subject. It may not be universal, but it is a safe rule—remove the cause, and nature will correct the pathology.

The intelligence of a community can be measured by the number that are wearing glasses. This can easily be verified by visiting any old college town. The eyes of school children have been shamefully neglected because only *twelve* out of one hundred are born with normal eyes. The errors of refraction exist, even if glasses are not worn. Will the discussants please explain? I have seen children who were kept out of school, assigned to a dark room, taking medicine (internal of course) for anemia, when a pair of glasses cured them. It is easy to remember that 88 percent of all eyes are too short, or too long or are irregular in curvatures. Nothing will correct such a physical defect but a pair of glasses. It is unfortunate to the children of school age that they must suffer for the errors, misunderstandings and superstition of their parents. Many are of the belief that glasses make one old, that the wearing of glasses compels one to always wear them. Glasses not only makes the wearer younger, but they act as a tonic to the eyes. Will the discussants please explain?

For convenience, the physically unfit are divided into the rich, the intermediate class and the poor. There should be a distinction between the worthy and the unworthy poor, because the deserving poor are generally a fine class, having

clean and pure blood, but unfortunately financially poor. There are not so many defectives among the rich because their children are well nourished, being an argument in favor of the malnutrition supporters. The children of the rich may suffer from excessive protein diet, causing irregularity in school attendance. The middle class is composed of our best citizenship —they are the bulwark of the nation and state, and should be physically normal. The poor—well, if this class is divided into the worthy and unworthy, I will gladly give my time to the former, but the latter, which make up the shiftless, uncertain and dishonest, are not worthy of scientific attention. Will the discussants please tell what to do with them?

We are not responsible for our existence, nor are any of the children in or out of school. It matters not to which class the parents may belong, if a child is physically crooked it should be made straight. Human passions are animal passions. Intermarriage may improve stock, as given in Plato's Ideal Republic; but eugenically speaking, the *desideratum* is not always reached, as illustrated in the mentality of our United States senate.

Money is essential to a livelihood, but the greatest pleasure in any of the branches in the practice of medicine is the gratitude of one's patients. To correct physical defects in the poor, and make them physically fit for school, and see them, by their own efforts, passing to the middle or dependable class, is certainly a pleasure, and compensates for all gratuitous work. If in the discussion of this subject means can be reached by which the poor of a community can be made physically fit for school work, and the teachers can cause a regeneration of previous mental impulses by instilling "pep" and ambition into those same delinquent patients, it will enhance the future good of the medical profession with more cash and fewer book accounts.

ADDENDA:—Most diseases are due to infection. It matters not whether the trouble lies in the teeth, tonsils, ears, eyes, heart, alimentary canal, kidneys or elsewhere, to be efficient for school work all physical defects should be corrected. Malnutrition may not be a disease, but the schools of the state have demonstrated that it can be cured with pure milk and hygenic living. Physicians and nurses will have the gratitude of future generations for their good work. Nurses would do well to advise the correction of defects at the beginning instead of at the close of the vacation. Nurses and family physicians need not be so positive in their assertions to parents and children. They are not expected to know as much on refraction as the ophthalmologist, nor of the nose and throat as the rhinologist. A little consideration of the specialist's opinion will not affect their standing with their families. To make children fit for school is to put them all upon the same equality. If all physical hindrances are corrected, the system will reconstruct because it constantly tends towards the normal.

Some physicians assert, "The doctor who depends upon iron tonics to overcome anemia; who uses sprays for chronic nasal catarrh; gargle for sore throats; internal medicines for rhinitis; who prescribes a dark room for sore eyes; who gives powders or pills for headache; who smokes into an ear for earache; who puts fresh beeksteak upon erysipelas; who prescribes cough medicines for a cough; who prescribes Lane's tea, or its like, for constipation; who prescribes diuretics for incontinence—in short, the doctor who is not 'up' on everything that pertains to medicine and surgery should prepare himself, or the public, as it is being educated, will consider the profession antiquated and not informed upon scientific medicine."

To throw oil upon the troubled waters, there are occasions when medicines are indicated. Patients at least get well from taking medicine, or in spite of the prescription. These laboratory men have surely thrown something into our quiet camp that smells. It is up to us to remove the same or prove its falsity.

DISCUSSION

DR. ADA E. SCHWEITZER (Indianapolis): Studies made by the Division of Child Hygiene upon the physical and mental status of children in our public schools show that children are frequently classed as retarded or defective mentally who after the removal of some physical handicap progress rapidly in the school curriculum. Although considerable attention has in recent years been given to the removal of defects of school children there still remains a large number who have had no especial attention given to health. Some of these children are vigorous and capable. Others are anemic, lack vitality and are unable to make satisfactory progress. The welfare of the latter class should be a sufficient incentive to regular and systematic health inspection of the children.

Among the causes of physical inequalities, we discover heredity, environment, malnutrition, habits and acquired defects.

Some children progress well along certain lines, but lack the ability to comprehend certain types of instruction. Nervous instability manifesting itself in the lack of coordination and failure of concentration is a defect which hinders the progress of many children. Children may inherit also physical deformities which make them inferior to other children because of the impossibility of certain kinds of activity.

The home atmosphere should be fresh and clean, both from the sanitary and social standpoint. Children do not thrive well in bad air or under unwholesome normal conditions. Quite

often a child's lack of progress at school may be traced to closed windows, to insufficient sleep, to incorrect habits of diet and exercise.

Probably the most talked of defect is poor nutrition. However, so many different standards have been used by persons who have set out to determine whether or not there are poorly nourished children in our schools that we are compelled always to ask the basis of the judgment. Even when we find children below weight for height we must know the reason for underweight. The reasons for underweight are many. It frequently happens that the child without regard to his social status is poorly nourished because he gets too little food or because he is not getting a well balanced diet. The pampered child of the rich parent is quite as likely to be poorly nourished from these causes as the child of the poor parents. In the case of the poor child, it is necessary to supply suitable food. An endeavor to do this in the case of all poorly nourished children has resulted in the establishment of milk lunches in a large number of our public schools. These, however, should be adapted to the conditions found. There are instances where they fail to give the desired results from the nutritional standpoint and these failures are potent arguments for a complete physical examination of the child and an investigation of his habits and history to determine the cause of poor nutrition.

Remedial defects should always be given attention before the child starts to school. Inability to measure up to correct standards of vision should mean a visit to the oculist. One authority states that 95 percent of school children have defective teeth. In our own work, we have found an average of two dental defects to every child. Some children are born defective in the mineral salts which are necessary to healthy teeth. Other children whose teeth originally are sound allow them to become defective through lack of care. Regular inspection of the teeth two or four times a year by a competent dentist, together with the correction of any defects found, would greatly improve this deplorable situation among our school children.

Among the acquired defects we find that we may trace many of them to neglected colds and other acute infections all too common in early childhood. If parents could only realize the many evils that follow in the train of these infections there would be no child willingly or willfully exposed to any of them. Frequent among these defects are poor hearing, enlarged tonsils, adenoid growths, chronic nervous irritability, inadequacy of heart valves or heart muscles and often chronic rheumatism and chronic colitis. Any of these physical defects will make the child possessing it less able to compete satisfactorily with his fellows.

Much greater interest and activity must be shown both by physicians and by lay persons before we shall even ameliorate these conditions. To get back to the original causes of many of them, we must begin with the education and the better scientific care of the expectant mother. The specialty of obstetrics must rank in importance with the specialty of surgery. The proper care and nutrition of both mother and child must in some way be provided for. As the writer has said, "That civilization is delinquent which neglects the best interests of its children."

DR. GEORGE V. CRING (Portland): I think that this subject is of extreme importance and the inequalities have been very well presented in detail by Dr. Spohn and Dr. Schweitzer, but it is one that has received far from the attention it deserves from the medical profession, and the practical side of it should be considered more seriously. I cannot see how any man having the education Indiana demands for a medical license would question the possibilities of great good and benefit to the individuals and to their respective communities from the medical examination of school children. Everyone surely must admit the existence of the inequalities and the desirability for correction. The recognition of defects, their correction, and the benefits and degree of perfection desired to be attained will vary greatly in different localities, depending upon both the professional and the lay education along health lines. The time is past when it is sane to think that all physicians have equal knowledge or ability or that they possess the same professional sincerity and moral consciousness which will lead them to do even the best they can under the existing circumstances.

Medical school inspection is not a fad nor an innovation but has been practiced for about thirty years or more. That it is not more popular and more successful does not count against it for the same holds true of modern medical science and I believe the same influences check its advance. What these influences are cannot be discussed in a few minutes, but are certainly worth the consideration of the Society. One of the greatest of these influences, I believe, is the lack of popular knowledge of conditions which call for the help of a medical adviser, and another, the knowledge of what constitutes or characterizes a capable and dependable physician.

I was interested to read in a recent number of the *Journal of the A. M. A.* the following extract which I think has considerable bearing upon this subject: "The Public Health Officer must sell the idea of the use of the practitioner for physical examinations and medical supervision as a means of preventing disease.

"It behooves the A. M. A. to have the largest concept of its responsibility to the public and the physicians at large in the matter of prevention. The science of medicine is today, perhaps, from five to ten years in advance of its general application. The A. M. A. is giving

the widest recognition to scientific advancement but it is not, I believe, pressing as energetically as it might for the wider application of the knowledge already at hand."

And also the following editorial in our last *Indiana State Journal*: "The success of the quacks and irregulars depends upon advertising, but even advertising would not have helped them if the regular medical profession had not failed to acquaint the public with the truth concerning scientific medicine. In reality, we have been too ethical in the sense that we have not taken the public into our confidence but have reasoned that the public ought to have sense enough to know that education, experience and training counts for more than ignorance, inexperience and no training."

The ideas that I wish to emphasize in this discussion are these:

1. It is to be taken for granted that these inequalities exist, are largely capable of correction and it is the general desire to have them corrected.

2. That in our medical school examinations we have the opportunity of discovering them and demonstrating their importance to all concerned.

3. That medical school examinations also afford a splendid way of (1) disseminating a popular knowledge of conditions which call for the help of a medical adviser; (2) of teaching the use of the practitioner for physical and mental examinations and medical supervision as a means of preventing disease; (3) of teaching what constitutes a capable and honorable physician; and (4) of advancing medical science by a better knowledge of the normal and its deviations.

However, to accomplish all these the medical examinations must approach as nearly as possible the ideal of the modern medical science as practiced in our best teaching hospitals and must not be of the type of inspection and propaganda of the poor medical practice and of the quack and charlatan who without education or equipment claims to be able to diagnose and supervise health conditions without a thorough examination of the individual.

I wish to commend the work of the child welfare department of the State Board of Health as Dr. Schweitzer is putting into practice the best of today's knowledge and raising the standard of work done in this line in the state in the counties visited.

DR. A. W. BRAYTON (Indianapolis): Dr. Schweitzer is doing great work and anything that is doing good work for the children should be upheld. I believe a child's education should be thought of as soon as the child is born. It should be followed until he has gone as far as he is capable of going, or as far as his people are capable of pushing him. I urge upon you each and every one to do all you can to get your children as far as you can in the higher realms of education. Without it this government would not be what it could be or should be.

DR. GEORGE W. SPOHN (closing): I do not believe there is any use in squandering money on children unless they have ability. Let them have ability and then spend money; otherwise not. Practically every school in the city has a room and some three, or four in a department for defectives. Thank fortune, my children are not in that group—but if they should be I would wish them to take the place where they belong. It is impossible to get away from inheritance.

Dr. Schweitzer is to be commended for her work. Not many in the state would give up their time for such small pay. It is a pleasure to correct physical defectives. Dr. Schweitzer and her nurses will reap their rewards hereafter.

SERUM PROPHYLAXIS OF MEASLES

The injection of serum obtained from donors was tried out during a recent epidemic of measles of moderate severity, in Rochester, Minnesota, and the results are reported by Morley D. McNeal, Rochester, Minnesota (*Journal A. M. A.*, Feb. 4, 1922). The donors were free from tuberculosis and syphilis, and had passed through fairly severe attacks of measles, without complications or sequelae. They were bled after an interval of five, seven or nine days from the disappearance of the fever. The serum was bottled in amounts of 6 c.c., preserved with 0.01 percent tricresol, and kept in the icebox until used. After varying periods following exposure, sixteen recipients were given 5 c.c. of the serum, injected into the muscles of the thigh. None of the children had ever had measles, although they had come in intimate contact with patients during the contagious period. Four of the sixteen developed an extremely mild type of measles, but no complications or sequelae. In three of the four patients, the incubation period was lengthened to nineteen days. Twelve children remained free from measles. One child contracted measles two months after successful inoculation; this suggests that the immunity does not persist longer than sixty days in some cases. The method recommends itself most highly for the prevention of measles during the period of danger, between the ages of 5 months and 6 years, in tuberculous children and in those physically below normal. In institutions in which large numbers of frail children are intimately associated, the procedure would be of great value.

USE AND ABUSE OF VITAMINES

There probably never was a valuable scientific fact established through careful and accurate research work, medical or otherwise, which was not trailed in a remarkably short time by its abuses. Sometimes these untoward results were in the form of personal calumnies heaped upon the discoverer of a new scientific fact but more commonly the abuse takes the form of shrewd attempts to commercialize upon the philanthropic efforts of truly scientific investigators. There is very justly a taboo upon that medical man who refuses to divulge to his confreres any valuable discovery or information into which he has come, and yet no sooner is it announced than some (or many) powerful commercial organizations grab at the new opportunity to reap fresh financial gains therefrom. True enough, many pharmaceutical houses are willing and glad to aid the medical profession in the proper elucidation of a new product, with the elimination of the chaff from the wheat, but many are proverbially willing to sacrifice scientific fact for pecuniary returns.

So it is with the recently developed vitamines A, B, and C, and one cannot help rejoicing at the lie given to certain manufacturers' claims by the experimental studies of a group of proprietary vitamin products by Hess, Morre and Calvin[1]. Antiscorbutic studies were made upon guinea pigs, with three commercial products, metagen, vitamon and a product containing dried orange juice and dessicated pig's liver. Studies on the antineuritic, water soluble vitamin B were made with pigeons. From their work these investigators concluded that while the process of manufacture and subsequent aging of the concentrated vitamin products did not cause as much deterioration of the antineuritic as of the antiscorbutic properties, yet all the products were very low in antiscorbutic qualities. That all the known vitamins can be prepared for dispensing in a concentrated form which will be unaffected by drying, aging and oxidation, is, in the minds of those investigators, open to question. In fact they believe, with other students of the question, that, except to meet specific indications, as in times of famine and certain economic upheavals, such as in war, the best method of obtaining sufficient vitamins is through a proper selection of foods—in other words, from the dairy, the grocery, and the market, not from the drug store. Among the more potent antiscorbutic foods may be mentioned spinach, turnips, cabbage, tomatoes and the citrus fruits. Likewise the apple and the banana have strong antiscorbutic properties, the latter being especially adaptable since, in this country, at least, it is almost invariably consumed raw and not subjected to such degrees of temperature as needed for canning or dessication, with the consequent reduction in the amount of the antiscorbutic vitamin.

X-RAY AND CLINICAL FINDINGS IN NORMAL CHEST

(OF CHILDREN SIX TO TEN YEARS OF AGE)

The National Tuberculosis Association has completed some research work that is of much value in increasing our practical knowledge concerning the findings in the chest of normal children up to ten years of age. This knowledge is of particular interest in connection with our study of tuberculosis. In order to establish the x-ray and the clinical finding in a normal child up to ten years of age, three groups of well-known roentgenologists and clinicians were selected. While the value of roentgenography in determining the presence of pulmonary disease has long been recognized, yet much difference of opinion exists in the interpretation of findings, largely because no set observations have been made establishing the variations that may occur in the normal. To one observer, shadows noted are indicative of disease, to another they are not evidence of a pathological process; to one they represent lesions of clinical significance, to another they suggest changes of no moment. It is with a view to correcting these shortcomings that the research committee undertook its work, and an appropriation of twenty thousand dollars was set aside for the expenses of the work. After many months of independent work the members of this research committee in considering the chests of normal children between the ages of six and ten years exchanged conclusions that disclosed almost a unanimity of opinion.

In all, over five hundred children were examined. All children who showed signs of disease were excluded from the series. Individuals from various strata of society, foreign and native born, residents of urban and rural communities, school children and children residing in institutions, children exposed to tuberculosis and some without a history of such exposure, children with and without a history of

previous infectious diseases, all symptom free and all of an approximately normal weight and height for their ages were studied. A history of each individual was recorded and in making the examination of the chest care was always observed to have the child relaxed and to see that no cramped or unnatural posture was assumed, for, as is well known, faulty position may lead to findings that cause confusion in interpretation. In addition, a tuberculin test was made on every child. The clinical data were then assembled, and after the roentgenologist had interpreted his plate independently, the clinical and roentgenographic findings were correlated.

The facts detailed seem to indicate that clinically the ideal normal child is a hypothetic impossibility. Children apparently healthy, symptom free and active, show on careful examination many deviations from fixed standards; variations that must be interpreted as within physiological limits. The studies reported warrant the following conclusions:

(1) The data obtained on percussion and auscultation of the lungs of normal children show wide variations from a fixed standard. These variations are usual and are considered to be within normal limits.

(2) Inasmuch as the changes referred to are dependent often upon alterations that persist as the residua of past infections of the respiratory tract, it is obvious that a careful anamnesis, with special reference to all infections, is necessary if diagnostic errors are to be avoided. Even a history carefully taken is often unreliable, as minimal infections are soon forgotten by many and among the unintelligent classes even more significant indispositions are not readily recalled.

(3) Failure properly to evaluate these deviations from a fixed standard will often lead to the unwarranted diagnosis of disease and to even less justifiable treatment.

(4) With a proper appreciation of the widest variations that the normal may present from the ideal, the informed clinician is better able correctly to understand the findings of the roentgenologist, and each, cooperating with the other, is less liable to error.

(5) D'Espine's sign as indicative of enlarged tracheo-bronchial lymph nodes is of little value.

(6) Recognition of and familiarity with the foregoing data is of cardinal and practical importance to every patient, potential and established. Without a proper appreciation of the facts set forth, no intelligent differentiation between a normal and an abnormal respiratory tract can be made.

THE ST. LOUIS SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

The annual session of the American Medical Association held at St. Louis last month was notable in many respects. First, there was a very large attendance; second, the scientific work was of a high order; third, the Association, through its House of Delegates, accomplished much that is in the interest of the welfare of the individual practitioner.

The sections were well attended, some of them even being crowded, and the papers as well as discussions were of a high order of merit. An elaborate scientific exhibit, the best ever given by the Association, attracted much attention. Even the exhibitors made a special effort to show the effects of advancement in their several specialties, and some of the exhibits were of real scientific merit, especially those which showed the late advances in the use of roentgen and light therapy and the use of electric devices as aids in diagnosis.

In the House of Delegates much attention was centered upon the reports of the various councils and committees, and no little interest was shown in quite a large number of resolutions pertaining to State Medicine, vivisection, revision of the "code of ethics", and abolishment of political hospitals.

Among some of the important resolutions was one recommending that county medical societies be encouraged to make public declaration that their members are prepared and ready to conduct periodic medical examination of persons supposedly in health, it being understood that the indigent only shall be examined free of charge and that all others are expected to pay for such examinations.

Another resolution recommended the establishment of a bureau for consideration of legislation and medico-legal problems in which the whole medical profession may be interested. It will be the function of this bureau to coordinate the activities of the several constituent state associations, to ascertain and crystallize the opinions of the medical profession, and to represent the American Medical Association. In all probability this bureau will have Washington as its headquarters, though it may be considered advisable to have the bureau operate from the home office in Chicago.

The Shepherd-Towner law was branded as a product of political expediency, not in the interest of the public welfare but an imported socialistic scheme which unjustly and inequitably taxes the people of some of the states for the benefit of the people of other states for purposes which are lawful charges only upon the people of the said other states. The law was disapproved as a type of undesirable legislation which should be discouraged.

Of much interest to the medical profession and even the public is the resolution on the

Volstead Act which declares that the American Medical Association, representing a membership of over eighty-nine thousand physicians, appeals to the Secretary of the Treasury and to the Congress of the United States for relief from the present unsatisfactory conditions and recommends that provisions be made for supplying bonded whiskey *for medicinal use only* at a fixed retail price to be established by the government.

Concerning vivisection the Association went on record as endorsing the "open door" policy on the part of all institutions carrying on vivisection for research work, which in reality means the admission of properly endorsed and responsible officers of humane societies for the purpose of observation of such research work.

On the recommendation of the Judicial Council an amendment to the constitution covering the question of medical ethics was adopted. The amendment is as follows:

"Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional. That does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated. It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind, or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned. All other like self-laudations defy the traditions and lower the tone of any profession and so are intolerable. The most worthy and effective advertisement possible, even for a young physician, and especially with his brother physicians, is the establishment of a well-merited reputation for professional ability and fidelity. This cannot be forced, but must be the outcome of character and conduct. The publication or circulation of ordinary simple business cards, being a matter of personal taste, or local custom, and sometimes of convenience, is not *per se* improper. As implied, it is unprofessional to disregard local customs and offend recognized ideals in publishing or circulating such cards. It is unprofessional to promote radical cures; to boast of cures and secret methods of treatment or remedies; to exhibit certificates of skill or of success in the treatment of diseases; or to employ any methods to gain the attention of the public for the purpose of obtaining patients."

A number of resolutions concerning State Medicine were offered for adoption and finally the House of Delegates passed the following:

"The American Medical Association hereby declares its opposition to all forms of 'state medicine' because of the ultimate harm that would come thereby to the public weal through such form of medical practice. 'State medicine' is hereby defined for the purpose of this resolution to be any form of medical treatment, provided, conducted, controlled or subsidized by the federal or any state government, or municipality, excepting such service as is provided by the Army, Navy, or Public Health service, and that which is necessary for the control of communicable diseases, the treatment of mental disease, the treatment of the indigent sick, and such other services as may be approved by and administered under the direction of or by a local county medical society, and are not disapproved by the state medical society of which it is a component part."

The selection of San Francisco as the place for holding the 1923 session, while representing the majority vote of the House of Delegates, was not satisfactory to a respectable minority that preferred Atlantic City. However, as the California medical profession seems to be having a hard fight against the pseudo-medical cults, it was thought that the moral support given by the great American Medical Association in holding its next annual session on the Pacific Slope is justified.

The selection of Dr. Ray Lyman Wilbur as president of the Association meets with general approval.

DIVISION OF FEES

There is no question but that division of fees under one guise or another is practiced by a considerable number of Indiana physicians, and it is surprising how some men can ease their consciences by making the plea that they are paying for the services of assistants (the referring physician) or merely collecting fees for others. In a few instances the surgeon or specialist makes no pretence of covering up his practices and freely admits that he is paying to get business. In fact some surgeons frankly state that in order to get business they are forced to buy it by commissions. On the other hand, there are enough general physicians without moral stamina sufficient to guide them along ethical planes who unhesitatingly say that they take their patients where they can get a "rake off."

This whole subject has been argued so much that little more can be added. The division of fees in any guise is a species of dishonesty which should not and will not be practiced by those who desire to be conscientious as well as ethical in the practice of medicine. The general physician is entitled to just compensation for any services that are rendered, and all too frequently he is illy paid, but not once in a thousand times is any one to blame but himself because he is not adequately paid. If he will not place a proper estimate upon the value of his services he cannot expect the patients to do it for him, and it is an admission of weakness to ask the surgeon to fix fees for him. In reality much of the division of fees as ordinarily practiced is not a recognition of the value of the services rendered by the referring physician but a bribe to insure further business. We have even heard it said that there are certain physicians who give ministers twenty-five dollars for every major surgical case referred, and the

wonder to us is that the same surgeons do not have paid agents out soliciting business.

The American College of Surgeons and practically all of the state medical associations have taken a decided stand in opposition to division of fees in any form, but despite all this opposition the practice has not been wiped out, though we are satisfied that it is more limited than it was a few years ago and more largely confined to a class of physicians whose standing in good medical circles is seriously questioned. Just at the present time we are interested in an amendment to the constitution of the Kentucky State Medical Society which says that no physician may become a member of any one of the component county societies of the Kentucky State Medical Association unless he shall sign and keep inviolate the following pledge:

"I hereby promise upon my honor as a gentleman that I will not, so long as I am a member of the Kentucky State Medical Association, practice division of fees in any form; neither by collecting fees from others referring patients to me nor by permitting them to collect my fees for me; nor will I make joint fees with physicians or surgeons referring patients to me for operation or consultation; neither will I in any way, directly or indirectly, compensate anyone referring patients to me nor will I utilize any man as an assistant as a subterfuge for this purpose."

In commenting on this the bulletin of the American Medical Association says that it may be questioned if this pledge imposes any more binding obligation upon the society member than does the oath to which he is supposed to have subscribed when he became a doctor. It is doubtful if the piling up of additional pledges will have much deterrent influence on the man who will do things that are clearly wrong. In fact, the doctor who has a screw loose in his moral make-up will not be deterred from the practice of division of fees no matter how many pledges he signs. He has no hesitancy in signing and breaking a pledge, for his conscience is elastic enough to cover any breach in his ethical or moral conduct. The Indiana State Medical Association went on record as opposed to the division of fees under any guise, but we venture to say that the action taken, while crystallizing sentiment against a pernicious practice, has not been the means of stopping it, though we believe that increasing knowledge of the public concerning the matter has had a tendency to lessen appreciably the practice, and it is this latter factor which is going to solve the question eventually. When the public gets fully wise to the fact that their ills, for the most part, are being bartered to the highest bidder, with little or no respect for quality or character of the services rendered, we can depend upon it that the division of fees will come very near to being wiped out entirely.

EDITORIAL NOTES

DEAR DOCTOR:

THE JOURNAL and the Cooperative Medical Advertising Bureau of Chicago maintain a Service Department to answer inquiries from you about pharmaceuticals, surgical instruments and other manufactured products, such as soaps, clothing, automobiles, etc., which you may need in your home, office, sanitarium or hospital.

We invite and urge you to use this Service.

It is absolutely FREE to you.

The Cooperative Bureau is equipped with catalogues and price lists of manufacturers, and can supply you information by return mail.

Perhaps you want a certain kind of instrument which is not advertised in THE JOURNAL, and do not know where to secure it; or do not know where to obtain some automobile supplies you need. This Service Bureau will give you the information.

Whenever possible, the goods will be advertised in our pages; but if they are not, we urge you to ask THE JOURNAL about them, or write direct to the Cooperative Medical Advertising Bureau, 535 N. Dearborn St., Chicago, Illinois.

We want THE JOURNAL to serve YOU.

PHYSICIANS generally will approve the publication of a lay medical magazine by the American Medical Association. Authorization of this project was given by the House of Delegates at the St. Louis session. The object of such a magazine is to give the public dependable knowledge concerning the health and how to care for it.

THE annual dues to the American Medical Association may be reduced if in the judgment of the board of trustees such reduction is justifiable. It is very evident that such a move was contemplated when the trustees urged the adoption of a resolution by the House of Delegates giving power to change the amount of the annual dues so that they shall not be less than five dollars nor more than six dollars per annum.

IN the death of Dr. J. N. McCormack of Louisville, Ky., on May 4, the medical profession loses one of its most prominent members, and one who probably has done more for public health work and the highest ideals of medical practice than anyone in the country. He not only served his own state for a great many years in public health work but for a number of years he was actively identified with the American Medical Association in many important capacities, not the least of which was his service in traveling widely throughout the United States in establishing an approved form of medical organization. In fact it may be said that his entire life was devoted to constructive work in the interests of public health and the higher aims and objects of the medical profession.

DR. JOHN A. WYETH, the well-known surgeon in New York City, died suddenly of heart disease on May 28th at seventy-seven years of age. Dr. Wyeth was not only a noted surgeon and the author of a text book and numerous

monographs on surgery but was a conspicuous figure in the development of American medicine. He was president of the American Medical Association in 1901, and has been honored a great many times in other ways by the medical profession. Indiana physicians have cause to remember him for the notable address delivered at the first South Bend session of the Indiana State Medical Association, where he was presented with a silver loving cup in appreciation of his talents and the very warm friendship that he held for a very large number of Indiana physicians,—a friendship that continued to his death.

IN the Hygienic Laboratory of the U. S. Public Health Service, during the last three years, examination has been made of all of the lots of commercial arshpenamin and neo-arsphenamin manufactured in the United States to note deterioration. In no instance was a lot of arsphenamin encountered which could be definitely said to have deteriorated, whereas a rather large percentage of the lots of neo-arsphenamin were found to have deteriorated since their first examination. Therefore, the following conclusions have been drawn: 1. That commercial neo-arsphenamin is a relatively unstable substance in the ampule. 2. Temperature is a potent factor in causing its deterioration. 3. It is advisable to keep it under storage conditions similar to those required for vaccines, until all the factors concerned in causing the deterioration of the compound are understood.

THE new president of the American Medical Association is Dr. Ray Lyman Wilbur, president of Stanford University. At St. Louis some objection was raised to the selection of Dr. Wilbur as president in view of the fact that for several years he has not been actively engaged in the practice of medicine. However, it should be remembered that from 1899, the date of his graduation from medical school, up to 1916 he not only was engaged in active medical practice but in teaching successively physiology and medicine in the Cooper Medical College and later the medical department of Stanford University. Since 1920 he has served on the Council on Medical Education and Hospitals of the American Medical Association and has shown conspicuous administrative ability and a gift for leadership. He has shown especial interest and sympathy with the problems of the general physician.

THE Muncie session of the Indiana State Medical Association should be a very successful one. In the first place, Muncie now has a live medical profession, showing unusual progressiveness and a spirit of harmony. The meetings of the Muncie Academy of Medicine are becoming rather famed because of their excellence and attendance from far and near. The coming session of the State Association should offer a scientific program second to nothing that has preceded it. Those who contemplate presenting papers should get in touch with the program committee at once. The final program will be published in the September number of THE JOURNAL. The *preliminary* program will appear in the August number. With our splendid Indiana roads, and now days every doctor owning an automobile, it is quite possible that a large percentage of those who attend the Muncie Session will enjoy going by automobile, though Muncie is not difficult to reach by railroad from most every section of the State.

WHEN we talk about grafts and foolish legislation we point with pride to Indiana's automobile headlight law. On the first of this year every automobile owner in Indiana was required to purchase and put on his automobile special headlight lenses. Of course these lenses cost from three to ten dollars per pair, and but a few manufacturers were able to comply with the requirements so very naturally they have enjoyed a nice income as a direct result of the law's exactions. It is barely possible that a fairly strict enforcement of the law would make us appreciate it, but, so far as we can see, there isn't a particle of effort made to see that automobiles are supplied with the required lenses or that the lights are focussed properly. In consequence we are troubled as much by glaring headlights as ever before. In fact, to the casual observer, absolutely no improvement in conditions can be noted. Thus we offer the query as to why the people of Indiana are made subjects of such fool legislation which apparently has benefited no one but the lens manufacturers.

THE *Journal of the American Medical Association* had net earnings of two hundred fifty thousand dollars during the year 1921. That is a tidy profit, but the funds are needed for carrying on the various projects inaugurated and supported by the Association. In fact, it is surprising how many activities of an exceedingly valuable nature to medical profession as well as public are carried on under the patronage of the American Medical Association. For instance, the work of the Council on Pharmacy and Chemistry in its splendid efforts for rational therapy has made its influence felt not only in this country but also broad. Then there is the educational service of the Propaganda Department which aims to investigate and expose the nostrum evil and quackery. The appropriations for special journals, and for research work in numerous investigations make the work of the Association of great value, but these various undertakings require an abundance

of money and for that reason the profit accruing from the publication of *The Journal* is necessary.

IN the ninth of a series of five-minute health talks by Dr. Hermann M. Biggs, New York, sent out by radio, tourists and camping parties are warned to guard against impure water for drinking purposes. People invariably make provisions for proper clothing, cooking utensils, good things to eat, etc., before starting on camping trips, but usually depend on getting water "any place along the way". This is not a good policy, as *safe* water is not always to be found when one wants it most. With the ever increasing number of campers, fishermen and hunters, there is a corresponding greater chance for the pollution of streams, thus rendering unsafe for drinking such surface water as found in springs, streams, ponds, etc. Attention is called to the fact that even the clear, sparkling water found in brook or spring may be polluted with the germs of typhoid. Campers are urged to get water from springs quite distant from dwellings and camps, and, when in the least doubt about the safety of the water, enough for the day should be boiled for five minutes over the camp fire, cooled in a cold stream, and kept tightly corked. Physicians would do well to speak a warning word on this subject to the laity.

ACCORDING to the report of the Committee on Legislation of the New York State Medical Society, the State of New York has less than one thousand chiropractors and about nine thousand regular practitioners of medicine who are members of the State society. The chiropractors alone spend from thirty to fifty thousand dollars a year to maintain their legislative lobby, which means a contribution from each chiropractor of from thirty to fifty dollars a year. Contrast that with seven cents a year paid by each member of the medical society of the State of New York. Practically the same state of affairs exists in every other state of the Union and exists in Indiana where the conditions are even more deplorable. It is known that the chiropractors spend several thousand dollars a year in legislative and propaganda work in Indiana, and for many years the legislative committee of the Indiana State Medical Association has spent less than one hundred dollars per year, and that merely for a little stationery, postage and telegrams while the legislature was in session. Is it any wonder that the chiropractors accomplish results? Further comment is unnecessary.

THE American Medical Association defines state medicine as "any form of medical treatment provided, conducted, controlled, or subsidized by the federal or any state government or municipality, except such service as is provided by the Army, Navy or Public Health Service and that which is necessary for the control of communicable diseases, the treatment of mental diseases, the treatment of indigent sick and such other services as may be approved by and administered under the direction of a local county medical society and are not disapproved by the state medical society of which it is a component part." This was a compromise measure to take the place of a number of resolutions concerning state medicine that were introduced in the House of Delegates at the St. Louis session. In reality what the Association should have done was to have put itself on record as opposed to any treatment furnished or controlled by federal, state or municipal authorities which is given or offered to any but the indigent, and is in direct competition with individual practitioners of medicine. The Association might have gone a step further and put itself on record as to the reasons why opposition is offered to state medicine.

THE board of trustees of the University of Cincinnati has adopted a resolution re-affirming its purpose to establish a pay ward at its hospital and to permit surgeons of the staff of the medical college to operate private patients there and to charge for the operations. The resolution was adopted in answer to an objection raised a few months ago by a leading Cincinnati physician in an address before the members of the Cincinnati Academy of Medicine. From this we are led to believe that so far as the University of Cincinnati is concerned the wishes of the medical profession as a whole are not to be considered in framing the policies of the medical department of that institution. Our conception of a hospital in connection with the University is that it is for purely teaching purposes, and as there are enough indigent patients to more than fill the wants of the teaching force of the medical department of the University it seems unnecessary to either throw down the bars for the admission of patients able to pay or to try to increase the income and prestige of the hospital and incidentally the prestige of the members of the medical and surgical staff of the hospital by admitting pay patients.

THE narcotic drug question is receiving serious consideration in the East, particularly in New York State. That other states will have to contend with the question is a foregone conclusion, and it is well to bear in mind that there are sinister influences at work to put the narcotic drug control in the hands of commercial interests and make it possible for drug addicts to be served, while at the same time the members of the medical profession are seriously handicapped in the legitimate prescribing and

use of narcotics of any kind. The idea of committing all drug addicts to public and private hospitals or sanitaria where narcotics may be administered in any amount, without any check being placed upon the practice, is in itself a dangerous proposition, but when this sort of an arrangement is proposed in connection with the further provision that physicians be obliged to keep records for every dose of a narcotic administered, prescribed or dispensed, whether directly or indirectly, is a discrimination which is as unfair as it is iniquitous. The control of drug addiction is a difficult one to regulate, but there is no reason why the matter should be commercialized by either public or private sanitaria.

THE decision on the part of the American Medical Association to establish a central bureau for consideration of legislation is a step that should have been taken long ago. All legislative matters pertaining to medicine or the practice of medicine should receive the careful consideration of a bureau representing the entire medical profession of the United States, and this bureau should be composed of permanent members who are well qualified for the position. In reality this bureau will take the place of a paid lobby in its endeavors to acquaint congressmen and legislators with pertinent facts concerning contemplated legislation that affects the medical profession or the practice of medicine either directly or indirectly. The reason that Congress and the various state legislatures have a tendency to consider some proposed legislation that is most obnoxious and injurious to public welfare is because such proposed legislation is represented by those who are interested in it for personal and selfish reasons and heretofore but little opposition has been offered by a united medical profession. It is time for medical men to wake up and present a solid front against all forms of vicious legislation which affect the medical profession individually or collectively, or the practice of medicine.

WE never have approved the Volstead Act and always have felt that the act represented the opinion of a minority of the people of this country. However, the Volstead Act is the law of the land and even its incomplete enforcement has resulted in untold benefit to the country as a whole. Furthermore, a law to be effective must be enforced, and we have no quarrel with those who desire the enforcement of the Volstead Act in a fair and honorable way. Therefore, we look with disfavor upon the action of the House of Delegates at the St. Louis session of the American Medical Association in passing a resolution calling upon the Secretary of the Treasury and the Congress of the United States for the adoption of provisions for supplying bonded whiskey for medicinal use only at a fixed retail price to be established by the government. In its ultimate analysis this simply means that a large number and perhaps a majority of the physicians of this country will become licensed bootleggers. The editor of THE JOURNAL does not remember ever to have refused a drink, and does not refuse one now if he can satisfy himself that what he is offered is not "moonshine", or doctored with wood alcohol, but he is distinctly opposed to the idea that whiskey is necessary for medicinal purposes, or that the privilege of prescribing whiskey for medicinal purposes can be left to the discretion of the average physician who will be tempted to prescribe whiskey as a beverage on the spurious plea that it is needed as a medicine. On the whole we believe that the action of the American Medical Association at the St. Louis session is not in keeping with the high ideals of our profession, for while the conscientious physician will not abuse any privilege accorded him in the prescribing of whiskey for medicinal use, there are countless thousands who will take advantage of the situation and become nothing better than ordinary bootleggers who purvey whiskey for a price.

AGAIN the stupendous work carried on directly and indirectly by the Rockefeller Foundation, through its departmental agencies, the International Health Board, the China Medical Board, and the Division of Medical Education, is brought to our attention through their annual report, summarized as follows:

Continued a quarter-million annual appropriation to the School of Hygiene and Public Health of Johns Hopkins University;
Pledged two millions to Harvard for a school of health;
Contributed to public health training in Czechoslovakia, Brazil, and the United States;
Aided the Pasteur Institute of Paris to recruit and train personnel;
Promoted the cause of nurse training in America and Europe;
Underwrote an experimental pay clinic in the Cornell Medical School;
Formally opened a complete modern medical school and hospital in Peking;
Assisted twenty-five other medical centers in China;
Promised a million dollars for the medical school of Columbia University;
Contracted to appropriate three and one half millions for the rebuilding and reorganization of the medical school and hospital of the Free University of Brussels;
Made surveys of medical schools in Japan, China, the Philippines, Indo-China, Straits Settlements, Siam, India, Syria, and Turkey;
Supplied American and British medical journals to 112 medical libraries on the continent;
Supplemented the laboratory equipment and supplies of five medical schools in Central Europe;
Defrayed the expenses of commissions from Great Britain, Belgium, Serbia, and Brazil;
Provided 157 fellowships in hygiene, medicine, physics, and chemistry, to representatives of eighteen countries;

Continued a campaign against yellow fever in Mexico, Central and South America;
Prosecuted demonstrations in the control of malaria in ten states;
Co-operated in hookworm work in nineteen governmental areas;
Participated in rural health demonstrations in seventy-seven American counties and in Brazil;
Neared the goal of transferring to French agencies an anti-tuberculosis organization in France;
Provided experts in medical education and public health for counsel and surveys in many parts of the world, and rendered sundry minor services to governments and voluntary societies.

CONCERNING the question of socializing medicine the *Ohio State Journal* has some pertinent comments concerning the uplift schemes masquerading under the term conservation, prevention, promotion, preservation, protection, correction, etc. Too frequently these movements, though unselfishly conceived and carried forward with unquestionable motives, lead to all sorts of abuses and even failures. Too frequently is medical service exploited in return for self gratification. Although medical service is being commandeered the public gains the impression that through failure on the part of the profession these spasmodic, periodic efforts in public education and treatment are necessary, whereas in many instances they are only satisfying the whims of chronic reformers and uplifters. Physicians and surgeons should be praised rather than censured for giving freely of their time and service in worthy practical causes, but special public health movements, campaigns and clinics may sometimes serve as subtle propaganda for individuals, and feeders for individual practice.

"If only the vast funds and unlimited energy along these lines were used in purely educational efforts; if the public could be taught that regular, frequent and thorough medical examination are necessary, and that even apparently trivial ailments should be promptly and properly treated, thus preventing later suffering, malignancy and premature death; if the public could be educated to avoid the quack, the pretender, the incompetent; to fear and avoid self-diagnosis and self-treatment; if the inefficiency and danger of cure-alls and single-method therapy for all ailments could become common knowledge, there would be little if any excuse for the multitudinous socialized schemes for the cure of human ills.

"These statements are made with the assumption that the individual physician will recognize his obligations to his patient and to the public. As one eminent public health official recently said to the writer: 'The medical profession is not only responsive to the value of public health work as a vital and necessary effort in education and prevention but it has long advocated such principle as a duty to the public. However, we have a right to expect that if we can educate the public to frequent physical examinations and to expect and demand competent service for medical and surgical ills rather than to rely on blatant claims of quacks and cultists; that genuine and conscientious service will be rendered. If each physician and surgeon would do his very best in each case, if he will be consistently thorough with each patient, there would be fewer followers of senseless frauds and fads.'"

DEATHS

D. D. CLARK, M.D., died at his home in Decatur, May 1 at the age of 55 years. Dr. Clark graduated from the Fort Wayne College of Medicine in 1891.

JOHN F. BENHAM, M.D., died at his home in Mooresville, May 11, following a brief illness. Dr. Benham was a graduate of the Medical College of Ohio, Cincinnati.

ELI BROWN, M.D., died at his home in Thorntown, May 10, at the age of seventy-six years. Dr. Brown graduated from the Eclectic Medical College of Cincinnati in 1879.

J. W. BIRCHFIELD, M.D., died at Hemlock, May 11, at the age of sixty years. Dr. Birchfield was a graduate of the Central College of Physicians and Surgeons, Indianapolis.

GEORGE W. FLEMING, M.D., died at his home in Shelbyville, May 3. Dr. Fleming graduated from the Bellevue Hospital Medical College, New York, in 1868. He was seventy-nine years of age.

CHARLES D. UMBERHINE, M.D., died at his home in Mechanicsburg, May 12. Dr. Umberhine was fifty-nine years of age. He graduated from the Rush Medical College, Chicago, in 1885, and was a member of the Indiana State Medical Association and the American Medical Association.

IRVIN O. ALLEN, M.D., of Bath, died April 27, at the age of fifty-seven years. Dr. Allen graduated from the Louisville Medical College, Kentucky, in 1898. He was a member of the Franklin County Medical Society, the Indiana State Medical Association and the American Medical Association.

MARIA JESSUP, M.D., of Fairfield, died May 5 at the age of 76 years. Dr. Jessup was a member of the Marion County Medical Society, the Indiana State Medical Association, and the American Medical Association. She graduated from Northwestern University Woman's Medical College in 1887.

C. E. MILLIGAN, M.D., Winchester, died May 4, aged 59 years. Dr. Milligan was a graduate of the Physio-Medical College of Indiana, Indianapolis, in 1890. He was a member of the Randolph County Medical Society, the Indiana State Medical Association and the American Medical Association.

M. P. DIDLAKE, M.D., of Monticello, died May 12 at the age of 78 years. Dr. Didlake graduated from the Northwestern University School of Medicine, Chicago, in 1867. He was a member of the White County Medical Society, the Indiana State Medical Association and the American Medical Association.

JAMES H. CHRISTIE, M.D., died at the home of his son in Indianapolis, May 7, at the age of seventy-three years. Dr. Christie graduated from the Cincinnati College of Medicine and Surgery in 1870. He was a member of the Jefferson County Medical Society, the Indiana State Medical Association and the American Medical Association.

NEWS NOTES AND PERSONALS

Anything in the line of physicians' supplies or equipment may be obtained from advertisers in THE JOURNAL OF THE INDIANA STATE MEDICAL ASSOCIATION. Patronize these advertisers for it means a continuance of their advertising patronage, and the latter means a larger and better Journal for you.

THE LaPorte County Medical Society held its regular meeting at Michigan City, May 12.

DR. FAYE O. SCHENCK, of Crawfordsville, has announced his retirement from active practice.

DR. EMERY D. LUKENBILL of Portland and Miss Treva Steed of Redkey were married May 8.

THE next meeting of the Seventh District Medical Society will be held in Indianapolis, October 26.

NURSES of District No. 1, State Nurses' Association, held their annual convention at Bluffton, May 13.

DR. R. R. ACRE, of Evansville, and Miss Beulah Gibson, of Indianapolis, were married at Indianapolis recently.

DR. THEODORE V. PETRANOFF has been appointed assistant surgeon at the Wabash railway hospital, Peru.

THE contract has been let for the erection of a new county hospital at Greencastle, Indiana. $95,000 has been appropriated for the building.

THE Wabash County Medical Society held its meeting at Wabash, April 20. Papers were presented by Dr. Whisler and Dr. Walker, of Lafontaine.

THE Howard County Medical Society held its meeting at Kokomo, May 5. A paper on "Endocrines" was presented by Dr. R. E. McIndoo.

DR. C. B. THOMAS, of Plainfield, was made president of the Indiana Physico-Medical Association at the sixtieth annual convention held at Indianapolis, May 12.

CHIROPRACTORS practicing in Wisconsin cannot add the abbreviation "Dr." or "D. C." to their names as it is unlawful and in violation of the statutes.

CONGRESSIONAL action on the bill making immediately available $12,000,000 for construction of hospitals for former service men was completed May 6th.

AT a recent meeting of the Henry County Medical Society the regular meeting date was changed from the first Friday to the second Tuesday of each month.

DR. W. D. CALVIN of Fort Wayne has been appointed councilor for the Twelfth District Medical Society to fill out the unexpired term of Dr. E. E. Morgan, deceased.

THE Madison County Medical Society held a meeting at Elwood, May 10. Papers were presented by Dr. Frank Newcomer, of Elwood, and Dr. S. W. Miley, of Anderson.

THE Kosciusko County Medical Society held its regular monthly meeting at Warsaw, April 25. A paper on "Diabetes" was presented by Dr. W. B. Siders of Warsaw.

THE Third District Medical Society met May 4 at Paoli. Papers were presented by Dr. Green, of Pekin; Dr. Horrine, of Louisville, Ky., and Dr. Gillespie of Seymour.

THE regular meeting of the Huntington County Medical Society was held at Huntington, May 5. Dr. Charles Beall of Fort Wayne presented a paper on "Intestinal Troubles."

DR. C. E. HOWARD has severed his connections with Dr. M. E. Klingler in the Clinic at Garrett, and has opened offices in San Diego, California, where he will make his future home.

THE Boone County Medical Society held its regular meeting at Lebanon, May 2. Dr. L. D. Carter, of Indianapolis, presented a paper on "Psychoanalysis and Suggestive Therapeutics."

THE Randolph County Medical Society held its meeting at the Randolph County Hospital, Winchester, May 8. A paper on "Shall We Advertise" was presented by Dr. E. G. Reynard of Union City.

DR. WARFIELD T. LONGCOPE has been appointed professor of medicine at the Johns Hopkins University Medical Department and physician-in-chief at the Johns Hopkins Hospital, beginning on July 1.

THE regular monthly meeting of the Jay County Medical Society was held at Portland, May 11. Dr. W. D. Schwartz presented a paper on "Foreign Bodies" and Dr. J. E. Nixon presented a paper on "Fractures of the Femur."

DR. GEORGE E. DE SCHWEINITZ, of Philadelphia, was elected president, and Dr. Luther C. Peter, also of Philadelphia, was elected secretary of the International Congress of Ophthalmology which met in Washington, D. C., April 25th and 26th.

THE Eleventh Indiana Councilor District Medical Society held its twenty-seventh annual meeting at Huntington, May 18. A clinic on the diseases of children was held at the Huntington County Hospital with Dr. A. C. Costello, of St. Louis, in charge.

AT the fifty-sixth annual meeting of the Indiana Institute of Homeopathy, Dr. George Lowe of Indianapolis was elected president; Dr. Frank Eikenberry of Peru, vice-president; Dr. Archie Jones of LaGrange, secretary; and Dr. J P. Slabaugh of Nappanee, treasurer.

DR. S. D. MALOUF of Peru has gone abroad to take special work in the diseases of the kidneys and bladder. He expects to study at Paris and Rome. Dr. Malouf will return to this country about the middle of October and will then resume his practice of medicine at Peru.

PRESIDENT HARDING has transferred from the control of the U. S. Public Health Service to the U. S. Veterans' Bureau the hospitals operated by the former for the medical care and treatment of World War veterans. Fifty-seven hospitals have been turned over to the U. S. Veterans' Bureau.

THE following officers of the American Society for the Control of Cancer have been elected for the year 1922: Dr. Charles A. Powers, president; Dr. George E. Armstrong, Dr. Clement Cleveland, Dr. L. Farrand, Dr. Rudolph Mates, vice-presidents. Thomas M. Debevoise, secretary; and Dr. Calvert Brewster, treasurer.

A DECISION in the Ohio state court of appeals, which was affirmed by the state supreme court, ruled that chiropractors cannot practice in Ohio unless licensed to do so by the state medical board. The result is that chiropractors who are said to have been practicing in the state, without licenses, will be subjected to vigorous prosecution unless they secure licenses to practice.

AT the forty-fourth annual congress of the American Laryngological Association, held in Washington, D. C., May 1 to 3, the following officers were elected for the ensuing year: Dr. Emil Mayer, New York, president; Dr. George Fetterolf, Philadelphia, and Dr. L. B. Lockard, Denver, vice-presidents; Dr. George M. Coates, Philadelphia, secretary, and Dr. Joseph P. Clark, Boston, treasurer.

THE Marion County Tuberculosis Hospital, located just outside of Indianapolis, has started construction on three new units, one of which is a children's building planned to accommodate forty-four juvenile patients, and two units of twenty-four beds each for adult patients. Within the next few weeks construction will be started on a large unit to be used exclusively for colored patients.

THE American Legion is conducting a campaign to raise two million dollars to establish a camp for tuberculous ex-service men at Tupper Lake in the Adirondack Mountains. Twenty buildings on a 1200 acre site already have been purchased. It is planned to have the camp advanced enough to care for 1700 men during the first year. Headquarters are at the Astor Hotel, New York City.

IN addition to the articles enumerated in the May number, the following article was accepted during April for inclusion in New and Nonofficial Remedies: Intra Products Co., Ven Sterile Solution Procaine 1 per cent. During May the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies: G. W. Carnrick Co.: Epinephrine-G. W. C. Co., Epinephrine Chloride Solution-G. W. C. Co.;

Intra Products Co.: Phenolsulphonephthalein-Ipco, Ven Sterile Solution Phenolsulphonephthalein; Lederle Antitoxin Laboratories: Pollen Diagnostics-Lederle; H. K. Mulford Co.: Diphtheria Toxin-Antitoxin Mixture—Mulford; National Aniline and Chemical Works: Neutral Acriflavine-Heyl, Tablets Neutral Acriflavine-Heyl, 0.1 Gm. (1½ grs.), Neutral Acriflavine-Heyl Throat Tablets, Neutral Acriflavine-Heyl "Pro Injectione" 0.5 Gm. vials, Neutral Acriflavine-Heyl "Pro Injectione" 1.0 Gm. vials; Winthrop Chemical Co.: Luminal Tablets ¼ grain.

UNDER the auspices of the Indiana State Board of Health and the Indianapolis Board of Health, in cooperation with all civic and community organizations of Indianapolis, the National Health Exposition Association put on an Indiana Health Exposition at the State Fair Ground, Indianapolis, May 19 to 27 inclusive. The program included motion pictures, musical numbers, pageants, demonstrations of various sorts, exhibits, and lectures and addresses by noted health workers. Dr. Frank B. Wynn served as chairman of the Educational Exhibit Committee; Dr. W. N. Wishard, chairman Pre-Exposition Sale of Tickets Committee; Dr. C. S. Woods, chairman Program Committee; Dr. Charles P. Emerson, chairman Collaborating Committee; Dr. R. E. Whitehead, chairman Speakers Committee; Mrs. Jane Teare Dahlman, Educational Director; R. E. Logsdon, Managing Director, and John A. McKeown, Associate Director. Friday, May 19, was known as Public School Day; Saturday, James Whitcomb Riley Day; Monday, Indiana Day; Tuesday afternoon, Women's Club Day; Tuesday evening, Men's Club Night; Wednesday afternoon, Doctors' and Nurses' Day; Wednesday evening, Personal Hygiene Night; Thursday afternoon, Oral Hygiene Day; Thursday evening, Civic Clubs' Night; Friday afternoon, Industrial Hygiene Day; Friday evening, Rural Health Problem Night; Saturday afternoon, Indianapolis Day; Saturday evening, Indianapolis Night.

The aim of the Exposition was the education of the public in disease prevention, and it is estimated that three hours devoted to the study of the exhibits and displays would provide the average citizen with a liberal education in how organization and government provide for the care of community health and at the same time how the individual in his daily and family life may escape disease.

Following is the registration of Indiana physicians at the St. Louis session of the American Medical Association:

Baker, Clarence S., Evansville. Baldridge, Ezra R., Terre Haute. Bannon, F. R., Kokomo. Beasley, Thos. J., Indianapolis. Bowers, H. C., Akron. Bradfield, John Logansport. NINTH COUNCILOR DISTRICT

The annual meeting of the Ninth Councilor District of the Indiana State Medical Association was held at Crawfordsville on May 17, under the direction of Dr. A. C. Arnett, Lafayette, President, and Dr. Thos. L. Cooksey, Secretary-Treasurer. The meeting opened at 1:30 p. m. with an address of welcome by Mayor Earl Berry. Scientific papers were presented as follows: The Scope of Urology, Dr. A. M. Sullivan, South Bend; Comparative Anatomy of the Eye, Dr. George F. Keiper, Lafayette; The Occiput Poster Position (demonstrated with lantern slides), Dr. Edward Lyman Cornell, Chicago.

The meeting closed with a banquet in the evening.

TIPPECANOE COUNTY

After a six o'clock luncheon at the Hotel Lahr Lafayette, the April 25 meeting of the Tippecanoe County Medical Society was called to order by President Ruschil. Regular Order of Business dispensed and Dr. John A. MacDonald of Indianapolis read a very concise paper on "Affections of the Mediastinum" which was illustrated by lantern slides.

SYNOPSIS: This region has been given scant consideration compared to its importance. Affections not rare nor impossible of elicitation. Mediastinum includes all structures in chest except lungs; is divided into four parts,—superior, middle, inferior and posterior. Examination: Four cardinal symptoms: dyspnea, pain, cough and expectoration. Dyspnea most common, worst form due to glandular enlargement with pressure. Cough almost constant, but varies in form and degree. Pain, if severe, usually means plura involved. Most always present in cases of tumors and aneurysms. Expectoration, any variety may be present. Pressure symptoms vary according to location, as aphonia, hoarseness, difficult swallowing, disturbances due to pressure on pneumogastric, pressure on blood vessels producing venous stasis with cerebral symptoms. Physical signs disappointing, but may have bulging, displaced apex beat or abnormal contour. Findings on palpation and percussion not essentially different from those elicited in other chest disorders. X-ray most valuable aid in diagnosis and should be utilized. Floroscoping unreliable. Diagnosis made by X-ray plates along with subjective symptoms and objective findings. *Inflammation*: Acute or chronic. Acute from trauma or from other adjacent nearby infections, or localized from general septicemia. Chronic as result of carcinoma, sarcoma, lukemia, adenopathy, tuberculosis or syphilis. *Tumors*: Benign and malignant. All essentially malignant because eventually become so. Benign not common though have fibroma, lipoma, cysts. Dermoid cysts most common. Of malignant, sarcoma most common with most frequent type being lympho-sarcoma. Produce

symptoms by pressure on adjacent structures, or by pressure on nerves that control distant structures. Carcinoma, primary or secondary, has more of tendency to break down and form cavities than do sarcoma.

DISCUSSION: Dr. Lairy.—Might add the finding of thymus gland in the young which is often the cause of sudden death. Mentioned a case of this kind coincident with exophthalmic goitre.

Dr. Pyke reported case of young man aged twenty with persistent cough which X-ray examination showed aneurysm size of orange. Patient couldn't be convinced, refused treatment and passed from observation, but had been heard of going from clinic to clinic.

Dr. Arnett offered the following resolution:

WHEREAS, Effort is now being made in this community and in the surrounding communities to aid in financing the improvements in our two local hospitals; and

WHEREAS, All the funds thus collected are to be expended locally; and

WHEREAS, For the past forty years this community and the surrounding communities have depended on these local hospitals and will continue to depend upon them for their needs in accident and sickness in the future; and

WHEREAS, At this time an effort is also being made to raise funds in this community to be used in the erection of a hospital at Indianapolis known as the Riley Memorial Hospital;

THEREFORE, Be It Resolved, That this Society feels it is in duty bound to advocate aid in the cause of the local hospitals, and to urge that whatever money is being given now or at any future time, be given to aid our two local hospitals rather than to give money to an Indianapolis hospital which can never be of direct local benefit to this community.

Be It Further Resolved, That a copy of this resolution be spread upon the minutes of this Society and that a copy be sent to the Home Hospital and to the St. Elizabeth Hospital of this city.

Motion to adopt the resolution made by Dr. Levering, seconded by numerous others and unanimously carried.

At this point the minutes of the previous meeting were read and approved without change.

Dr. Allen under the State Board of Health announced that the Child's Welfare Conference would be held here May 9 and 10 at which school age children would be weighed, measured, inspected and graded; and asked for the assistance of the local physicians.

Dr. W. S. Moffitt read a paper entitled "Personal Recollections of the 'Old Time Doctor'". This paper was so entertaining and so full of historical interest, that its text was ordered to be spread upon the minutes.

Adjourned.

WM. M. RESER, Secretary.

CORRESPONDENCE

THE DOCTOR'S REST AND RECREATION

Editor THE JOURNAL:

Some time ago the advertising editor of the "Journal of the American Medical Association" wrote to a number of physicians in regard to accepting advertisements showing where the tired physician could get rest and recreation. As many of our doctors in this state go to California and Florida for rest in the winter, both of which I have visited for that purpose, I wish to suggest another and better place which is easily accessible, and gives the added pleasure of a wonderful trip on a tropical sea. This trip can be made in four weeks or longer.

Leaving Indianapolis on March 8th we were within twenty-four hours in New Orleans, leaving behind a hail, rain and windstorm, and entering into Spring already established with the flowers in bloom, and sunshine making life worth while. On the next day we embarked on the Steamship "Zacapa" of the United Fruit Company, and for eight hours we were interested in the lovely panorama of the lower Mississippi river. This steamship line caters to the traveler's comfort in the Tropics, and with the use of the electric fan and the cold air duct you are able to keep your stateroom pleasant and comfortable even in the hottest of latitudes. Nearly three days after leaving New Orleans we entered the historic harbor of Havana. Five days in Havana was sufficient to see the sights of the place. Among the interesting places here I may mention the trip to the Casino, race track, an auto trip to the country showing the cultivation of tobacco, banana, pineapple and sugar-cane; a trip to the Toledo sugar mill where we saw the cane go in at one end and come out coarse brown sugar at the other end, ready to be sent to the United States for refinement. Other trips were made to the tropical gardens where beer was dispensed without cost for all who wished to drink, and yet no signs of any drunkenness. The remarkable thing was that there was only about a dozen people at the place, and these were all Americans. Other interesting trips included the Morro Castle, the Lighthouse, and Fort Cabannas. A river trip was made to see the national game, Jai Lai, which I think is one of the most exciting games I ever saw, at which most of the audience gamble, and which could be the most crooked of all gambling games. Facilities for shopping were most excellent and every lady in our party was delighted with the wonderful bargains in fans, perfume, toilet soap, and linens. The gentlemen were also delighted with the reasonable prices of the cigars as well as the other things to soothe and assuage a tropical thirst. Hotel prices here are high, but the cruise passengers without extra charge could remain on the boat, and if buying a ticket from port to port, a charge of two dollars ($2) per person a day is all that is needed to sleep on the boat. Excellent meals and sea-food dinners were had in the Cafe de Paris, Cosmopolita, Dos Hermanos, and the Cafe LaFayette.

Leaving Havana on the beautiful steamship "Ulua" of the United Fruit Company, which had on it about one hundred cruise passengers from New York, we were pleased to meet a friend of our Philippine days, Dr. Richard P. Strong, Professor of Tropical Medicine at Harvard University, who was on his way to establish The Gorgas Memorial Institute of Tropical Diseases in the City of Panama. Two days and a half more along the northern coast of Cuba brought us to the beautiful harbor of Port Antonio, Jamaica, the most beautiful spot of the West Indies. The place seemed to be most delightful to Hoosier eyes. I counted nine tropical fruits cooked, uncooked, or in sherbets on the bill-of-fare at the Hotel Titchfield. This is a most ideal spot to spend some time on account of the luxuriant foliage, the lovely breeze at evening and also the wonderful starry skies, revealing several thousand stars unseen in Indiana. Starting in the morning we took a four-hour auto trip across the island to Kingston. This is a mountainous trip and the mountains are as pretty as those of Switzerland. We stopped at the Castleton Gardens, where every known tropical plant grows. Kingston is hot during the middle of the day, before the sea breeze comes. It reminds you of Suez, Cawnpore, or Hong-Kong. The perspiration oozes through your clothes, and yet as soon as you relax in the shade of the Myrtle Bank Hotel you feel refreshed, and ready for another sightseeing or shopping trip. The ladies of the party enjoyed the many colored baskets, for here the most beautiful baskets in the world are made. I was much interested in a new tropical disease called "Alastran" which though never fatal shows similar clinical symptoms to smallpox, and the sufferer is miserable for many weeks with a terrible eruption. Dr. Strong located a fatal case of hookworm disease. It was fatal on account of the treatment by Chenopodium.

Shortly before our arrival a young girl lost her life by a large shark coming in the Kingston harbor and grabbing her while swimming. The shark was caught and put on exhibition and it certainly was a terrible creature. One of the older residents of the city said that it had been over forty years since this had occurred before. It did not seem to worry the brown boys as the natives dived every day for coins as usual.

Two and one-half days more brought us to the harbor of Christobal. It is hot in Panama and the lightest clothes are none too light, but the wonderful Hotel Washington and the cool breeze at night make life most pleasant.

Our party were guests at Fort Sherman, which is situated up in the hills. Here the breeze is strong and it is necessary to sleep with cover on you at night. In the shade you are cool at any hour of the day. A week here passed all too soon. Fishing is very good here, groupers, tarpon and amberjacks were

pulled out of the surf on the beach. Excellent fish are also found in the canal locks and along the Pacific Coast.

One day was devoted to an excursion trip to old Fort Lorenzo at the mouth of the Chagres river. This was the river the Spaniards used to bring the gold of Peru across the Isthmus and here can be seen thousands of cannon balls, hundreds of cannon and scores of dungeons.

A day at Ancon and Panama, both parts of one city, was delightfully spent in viewing the fortifications of old Panama, the wonderful cathedrals and the Ancon Hospital. It is a great pleasure to have Dr. Earheart and Dr. Clark, former Indianapolis men, to represent Indiana in such a wonderful hospital as they have there. The situation for the hospital is the most beautiful I have ever seen. Its equipment is perfect, and the results obtained there give its staff a reputation that extends from Central America down the coast of South America. It is an ideal situation for the study of tropical diseases.

The ladies agreed that this was the best place of the entire trip for Panama hats, Japanese and Chinese kimonos which were to be had at reasonable rates after much bargaining. The hotel rates at the Toivoli and the Washington at Christobal are reasonable, and the food at the government cafes is excellent and cheap.

Leaving Christobal on the "Atenas" of the United Fruit Company and in a little more than four days we were back again in New Orleans wishing we could start again and make the whole trip over. We have no regrets for making this lovely tropical trip. I am sure that any Hoosier physician would have much pleasure out of a trip of this kind more than the usual trip to California or Florida.

FRANK W. FOXWORTHY,
Indianapolis.

THE TRUTH ABOUT MEDICINES

NEW AND NONOFFICIAL REMEDIES

IZAL.—An albuminous emulsion, containing not less than 50 per cent. of "izal oil," obtained in the destruction of bituminous coal, and consists essentially of monatomic phenols boiling between 205 and 300 C. Izal is practically free from phenol and cresols. Izal is a germicide and disinfectant. The germicidal efficiency is claimed to be twelve times as great as that of any equal quantity of phenol, but it is stated to be less toxic than phenol. The Abbott Laboratories, Chicago.

IZAL DISINFECTANT POWDER.—Izal oil, 10 per cent; naphthalene, 5 per cent; inert, absorbent earth, 85 per cent. The Abbott Laboratories, Chicago.

POWDERED PROTEIN MILK-MERRELL-SOULE.—DRY PROTEIN MILK.—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 Gm. contains approximately: protein, 38 Gm.; butter fat, 27 Gm.; free lactic acid, 3 Gm.; lactose, 24 Gm., and ash, 5 Gm. Powdered protein milk is said to be useful for correcting intestinal disorders of infants and children. For the majority of conditions, powdered protein milk should be administered in small quantities according to the age and condition of the patient, after a period of starvation of from twelve to forty-eight hours. Merrell-Soule Sales Corp., Syracuse, N. Y.

SABROMIN.— CALBROBEN.— CALCIUM DIBROMBEHENATE.—Sabromin contains not less than 28.5 per cent. of bromine. Sabromin is not adapted to conditions in which a rapid saturation of the system with bromine is required. It is indicated in conditions in which the bromides cannot be administered for continued periods without gastric disturbance or in which brominism is caused readily. It is claimed that sabromin is of value in conditions in which a mild sedative action is desired, particularly in conditions requiring prolonged administration.

Dosage: from 0.3 to 1.2 Gm. Winthrop Chemical Co., Inc., New York. (*Jour. A. M. A.*, May 6, 1922, p. 1389).

Sabromin tablets, 8 grains. Winthrop Chemical Company, Inc., (*Jour. A. M. A.*, May 6, 1922, p. 1389).

IOTHION.— IOPROPANE.— DI-IODO-HYDROXY-PROPANE.—Iothion contains from 77 to 80 per cent. of iodine. It is used when it is desired to obtain the systemic effect of iodides by external application. Iothion is used in the form of iothion oil, in solution in alcohol or glycerin, or in the form of ointments containing from 5 to 20 per cent. of iothion. Winthrop Chemical Company, Inc., New York (*Jour. A. M. A.*, May 13, 1922, p. 1459).

IOTHION OIL.—Iothion, 10 parts; chloroform, 10 parts; olive oil, 80 parts. Winthrop Chemical Co., Inc., New York, (*Jour. A. M. A.*, May 13, 1922, p. 1459).

TYPHOID-PARATYPHOID VACCINE (Prophylactic) (See New and Nonofficial Remedies, 1922, p. 310).—A typhoid vaccine marketed in packages of three 1 Cc. bulbs, the first dose containing 500 million killed typhoid bacteria, 375 million killed paratyphoid A and 375 million killed paratyphoid B bacteria; the second and third doses each containing 1,000 million killed typhoid bacteria, 750 million killed paratyphoid B bacteria respectively. Parke, Davis & Co., Detroit, Mich.

PNEUMOCOCCUS VACCINE (4 TYPES) (See New and Nonofficial Remedies, 1922, p. 304).—A suspension of pneumococci, Types I, II, III and Group IV, in equal proportions, in physiologic solution of sodium chlorid, preserved with cresol, 0.3 per cent. Each cubic centimeter contains 3,000 million killed bacteria. Marketed in packages of four 1 Cc. bulbs; four 1 Cc. syringes; 5 Cc. vials and 20 Cc. vials, respectively. Parke, Davis and Co., Detroit, Mich.

STREPTOCOCCUS VACCINE POLYVALENT (SCARLATINA).—A streptococcus vaccine (See New and Nonofficial Remedies, 1922, p. 308), marketed in packages of four 1 Cc. bulbs, each cubic centimeter containing 1,000 million killed streptococci isolated from scarlatina cases; also marketed in packages of 4 Cc. syringes, in 5 Cc. vials and in 20 Cc. vials. Parke, Davis and Co., Detroit, Mich.

PERTUSSIS VACCINE.—A pertussis bacillus vaccine (See New and Nonofficial Remedies, 1922, p. 303), marketed in packages of four 1 Cc. bulbs, each cubic centimeter containing 4,000 million killed pertussis bacilli (Bordet); also marketed in packages of four 1 Cc. syringes, in 5 Cc. vials and 20 Cc. vials. Parke, Davis and Co., Detroit, Mich., (*Jour. A. M. A.*, May 13, 1922, p. 1459.)

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE-MULFORD.—T. A. MIXTURE-MULFORD.—Each Cc. of this mixture (See diphtheria antitoxin-toxin mixture, New and Nonofficial Remedies, 1922, p. 282) constitutes a single dose containing three lethal doses of toxin and 3.5 units of antitoxin. It is marketed in packages of three 1 Cc. vials; in packages of thirty 1 Cc. vials, and in packages of one 10 Cc. vial. H. K. Mulford Co., Philadelphia.

PHENOLSULPHONEPHTHALEIN-IPCO.—A brand of phenolsulphonephthalein-N.N.R. (See New and Nonofficial Remedies, 1922, p. 222). It is marketed in the form of Vensterile solution phenolsulphonephthalein, 1 Cc. representing phenolsulphonephthalein-Ipco 0.006 Gm. in the form of the monosodium salt. Intra Products Co., Denver., (*Jour. A. M. A.*, May 23, 1922, p. 1612.)

PROPAGANDA FOR REFORM

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the Federal authorities charged with the enforcement of the Food and Drugs Act:

Iron Elixir (Charles S. Miller), a dilute watery solution of sodium citrate and iron chlorid, with a slight trace of alcohol, sold as a cure for pimples and boils and as a blood purifier.

Vegetable Regulator (Charles S. Miller), an alkaline watery solution containing aloes and baking soda, claimed to be a remedy and cure for diseases of the liver, diseases pertaining to the stomach and bowels.

Diuretine (East India Medicine Co.), consisting of potassium acetate, buchu extract, a laxative plant drug, oil of juniper berries, sugar, alcohol and water and represented as a cure for Bright's disease and other conditions.

Bloodzone (East India Medicine Co.), consisting of extractives of plant drugs, including a laxative drug, sugar, alcohol and water and represented as a cure for syphilis, cancer, rheumatism, catarrh, boils, psoriasis, pimples and many other conditions.

Grantillas (Eneglotaria Medicine Co.), containing emodin-bearing plant extractives and cramp bark and claimed to be "the best existing uterine tonic", a first class general tonic in anemia and chlorosis and a cure for "Hysteria."

Winslow's Sarsaparilla Compound (Howard Drug and Medicine Co.), consisting essentially of extract of plant material, including sarsaparilla, potassium iodid, glycerin, alcohol and water and claimed to be a reliable remedy for scrofula, chronic ulcers, syphilitic affections, etc. (*Jour. A. M. A.*, May 6, 1922, p. 1407).

MORE MISBRANDED NOSTRUMS.—The following products have been the subject of prosecution by the federal authorities charged with the enforcement of the Food and Drugs Act, chiefly because the therapeutic claims made for them were unwarranted:

Compound Fluid Balmwort (The Blackburn Products Co.), consisting essentially of plant extractives, including bear-berry, a large proportion of sodium acetate, alcohol and water.

Whitlock's Child's Laxative (Whitlock Herb Medicine Co.), containing senna, Rochelle salt, sodium salicylate, soda, alcohol and water.

Whitlock's Cough Sirup (Whitlock Herb Medicine Co.), consisting of plant extractives, licorice, sugar, alcohol and water.

Whitlock's Cathartic Sirup (Whitlock Herb Medicine Co.), containing extracts of plants, including jalap, senna, fennel and peppermint, sugar, alcohol and water.

Whitlock's Nervine Pills (Whitlock Herb Medicine Co.), containing plant material, including asafetida, valerian, licorice and an ammonium compound.

Whitlock's Blood Pills (Whitlock Herb Medicine Co.), containing plant material, including red pepper, aloes, colocynth, and scammony.

Whitlock's Female Cordial (Whitlock Herb Medicine Co.), containing extracts of plants, including senna and jalap, alcohol, sugar and water.

Whitlock's Kidney and Gravel Medicine (Whitlock Herb Medicine Co.), containing volatile oils, including oil of sassafras, anise, and turpentine and alcohol.

Red Indian Liniment (Whitlock Herb Medicine Co.), containing oil of turpentine, acetic acid, ammonium chlorid, alcohol and water.

Whitlock's Worm Cordial (Whitlock Herb Medicine Co.), containing plant extractives, including spigelia and senna, glycerin, a small amount of salicylic acid, sugar, alcohol and water.

Whitlock's Nerve Pills (Whitlock Herb Medicine Co.), containing colchicin, asafetida and extract of hops.

Whitlock's Rheumatic Pills (Whitlock Herb Medicine Co.), containing colocynth, jalap and guaiac.

Whitlock's Kidney Pills (Whitlock Herb Medicine Co.), containing copaiba, extract of cubebs, a trace of oil of turpentine and magnesia. (*Jour. A. M. A.*, May 20, 1922, p. 1556.)

BOOK REVIEWS

EPIDEMIOLOGY AND PUBLIC HEALTH. A Text and Reference Book for Physicians, Medical Students and Health Workers. In Three Volumes. Vol. 1. Respiratory Infections. By Victor C. Vaughan, M.D., L.L.D., Chairman of the Division on Mental Sciences of the National Research Council. Assisted by Henry F. Vaughan, M.S., Dr.P.H., Commissioner of Health of the City of Detroit, and George T. Palmer, M.S., Dr.P.H., Epidemiologist for the Department of Public Health of the City of Detroit. Cloth. Price $9. Pp. 668, with 81 illustrations. St. Louis: C. V. Mosby Company, 1922.

This book by Vaughan is, of course, one of the most important contributions to American medical literature. The preface to the work is an outline of Vaughan's own life experience in so far as it pertains to epidemic disease. This is the most interesting and possibly the most valuable part of the book. The author has taken the opportunity to elaborate and develop his own ideas concerning the pneumonias, measles, German measles, small- with respiratory infections. Here we find chapters on albuminal diseases, pollinosis, the acute coryzas, the pneumonias, measles, German measles, smallpox, chickenpox, diphtheria, scarlet fever, mumps, whooping cough, influenza, tuberculosis, leprosy, cerebrospinal meningitis, poliomyelitis and glanders. It is presumed that Vaughn believes that all these infections take place through the respiratory tract—some exception might be taken to this idea.

The largest chapter in the volume deals with Influenza. It is interesting to note that the author's combative measures against this disease amount to practically nothing. He states: "We do not believe that the nose and throat prophylaxis is an effective weapon against influenza"; "The only motive for closing schools would seem to be that it can be done"; "Immunization, both as a preventive and curative treatment of influenza, has been tried, but the success of these measures has not been thoroughly established." The author is exaggerating when he states that "the diphtheria bacillus seems well nigh ubiquitous." Vaughan accepts the theory that the virus of scarlet fever is not contained in the epidermal scales thrown off in desqumation and he states that scarletina is "spread chiefly through fomites."

This book will impress students with the great importance of healthy carriers in the dissemination of respiratory infections.

THE PSYCHIC HEALTH OF JESUS. By Walter E. Bundy, Ph.D., Professor of the English Bible in DePauw University. New York: The MacMillan Company, 1922.

The author is a student of New Testament literature and not a specialist in mental diseases. When he attempts to controvert the allegations of Holtzman, Rasmussen and others that Christ was an ecstatic, an epileptic or a paranoiac he wades in beyond his depth. If one were forced to form his estimate of the psychic health of Jesus on a study of this book he would be forced to conclude that it was, to say the least, questionable. The book represents a vast amount of work and it will find many interested readers, but the Reviewer cannot but wonder as to the nature of the subconscious motive which animated the author.

THE SPLEEN AND SOME OF ITS DISEASES. By Sir Berkeley Moynihan, of Leeds, England. 129 Pages with 13 full page diagrams. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $5.00 net.

This book contains the material upon which the author based the Bradshaw Lecture delivered at the Royal College of Surgeons of England in December, 1920. Pernicious Anæmia, Leukæmia, Hodgkin's Disease, Splenic Anæmia, Hemolitic Jaundice, Gaucher's Disease, van Jaksch's Disease and Polycythæmia are all considered with their relationships to pathological changes in the spleen and the chances of relief from surgical intervention. The author rightly states with emphasis that "instead of searching only for the existence of this or that splenic disease, an inquiry should be directed to the functional capacity of all the organs likely to be deranged." This book should be studied by both the surgeon and the internist.

THE PRACTICAL MEDICINE SERIES. Volume 11, General Surgery. Edited by Albert J. Ochsner, M.D., F.R.M.S., L.L.D., F.A.C.S., Surgeon in Chief Augustana and St. Mary's of Nazareth Hospitals; Professor of Surgery in the Medical Department of the State University of Illinois. Series 1922. Price $2.50. Chicago: The Year Book Publishers.

Ochsner's abstracts and discussions of the surgical literature are now well known and their value is widely recognized. While these books are published primarily for the general practitioner, they have a distinct value for the specialist. The reviewer knows of no book that better covers a general review of the year's surgical literature than does this one.

THE SURGICAL CLINICS OF NORTH AMERICA. (Issued serially, one number every other month). Volume II Number I (The Philadelphia Number) 331 pages, with 145 illustrations. Per clinic year (February, 1922, to December, 1922). Paper $12.00 net; Cloth $16.00 net. Philadelphia and London: W. B. Saunders Company.

The Surgical Clinics of North America are still measuring up to their original high standard. The latest volume, the "Philadelphia Number", has among its contributors Deaver, Frazier, DaCosta and Muller—no abler group of surgeons is to be found in America. We strongly recommend these clinics to all those who are interested in the clinical side of surgery.

ABDOMINAL PAIN. By Prof. Dr. Norbert Ortner. Chief of the Second Medical Clinic at the University of Vienna. Authorized Translation by Wm. A. Brams, M.D., formerly Lieutenant Commander, Medical Corps, U. S. N., and Dr. Alfred P. Luger, First Assistant, Second Medical Clinic, University of Vienna. Cloth. Price $5.00. New York: Rebman Co., 1922.

Ortner is an internist but he deals with surgical conditions in an interesting and instructive manner. He considers a number of conditions which are not usually found in American text-books. Acute deficiency of the adrenals receives attention as an important cause of diffuse abdominal pain with shock. He remarks: "A condition which may cause confusion with general peritonitis is mesoperiarteritis nodosa." The book is replete with diagnostic signs which are unfamiliar to the Reviewer. For instance: "cyanosis of the anal region is a valuable sign in the diagnosis of intussusception"; "muscular rigidity is absent in a perforation of a pyloric carcinoma"; "an early and important symptom in pneumococcic peritonitis is diarrhœa." Speaking of the differentiation between perforative peritonitis and strangulation ileus, the author says: "If the rectal temperature is two or more degrees higher than the axillary, it is an almost certain sign of peritonitis." On page 11 he states: "I wish to emphasize the point that bloody stools are practically never seen in internal incarceration and have no connection with this type of obstruction of the small bowel"—this statement is incorrect. One reads on page 6: "A sign described by Wahl-Schlange's sign may be present," and on page 16 is mentioned "Wahls and Schlange's signs"—the translators, of course, knew what they were writing about.

MEDICAL AND SURGICAL REPORTS OF THE EPISCOPAL HOSPITAL. Volume V. Philadelphia: Press of Wm. J. Dornan, 1920.

"The publication of this volume has been made possible by the establishment of a Publication Fund by a generous friend of the hospital, the late Miss Harriet Blanchard." These Reports of the Episcopal Hospital were not published during the war, so this is the first volume since 1916. Thirty-four authors contribute articles on a wide variety of medical and surgical subjects. But a very few of these articles have been published in current periodicals. It is interesting to note that, despite the large number of contributors, the articles of Astley P. C. Ashurst fill at least a third of the volume. This book will find a place in every medical library that is at all complete.

HUMAN HEREDITY. By Casper L. Redfield, Author of "Control of Heredity," "Dynamic Evolution," "Great Men and How They Are Produced," Etc. Issued April, 1921. Cloth, 112 pages, $1.50. Chicago: Heredity Publishing Company, 1921.

The author does not value the teachings of either Darwin or Mendel. He believes that "powers developed by exercise in one generation are inherited by the next." He states: "In examining the pedigrees of intellectually eminent men I found that those born to fathers more than forty are more numerous than those born to fathers less than thirty." He gives an imposing list of famous men who were born to parents who were at or past middle life. The book is neither expensive nor long and can well be read by those interested in the study of heredity.

NEOPLASTIC DISEASES: A Treatise on Tumors. By James Ewing, M.D., Sc.D., Professor of Pathology at Cornell University Medical College, New York City. Second Edition, Revised and Enlarged. Octavo of 1,054 pages with 514 illustrations. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $12.00 net.

That a second edition of a work of this kind is called for within three years from the publication of the first is at once an evidence both of its popularity and its merit.

The most extensive changes have been made in the chapters on bone tumors and neurofibromatosis. Thirty-four illustrations and twenty-eight pages have been added. New references also have been added.

No small part of the value of this work, like that of its predecessor, lies in the splendid bibliography. The book bears every evidence of being the work of a painstaking, enthusiastic, experienced man and deserves a place in the library of every man interested in the subject of tumors—and all doctors are or should be.

RADIOGRAPHY IN THE EXAMINATION OF THE LIVER, GALL-BLADDER, AND BILE DUCTS. By Byron Knox, M.D., Hon. Radiographer, King's College, London, England. Cloth. Pp. 64 with 64 Illustrations. Price $2.50. C. V. Mosby Company, St. Louis.

Any work that aids in the differential diagnosis of lesions of the upper right abdominal quadrant is of distinct value, hence this brief resume of the anatomical considerations of the area, the pathology and chemical composition of gall-stones together with the results of an experimental investi-

Armour's LABORATORY PRODUCTS

Asthma and Hay Fever

Suprarenalin Solution and Ointment, 1:1000

Local application to eyes, nose and throat, hypodermatically 1:10000 solution into the arm or neck.

Suprarenalin designates the pure Suprarenal astringent hemostatic and pressor principle without preservatives.

In Obstetrics and Surgery

Pituitary Liquid, an uncontaminated solution of posterior Pituitary substance, standardized, ½ c. c. ampoules, obstetrical or surgical, 1 c. c. ampoules surgical or obstetrical.

Literature to physicians, pharmacists and hospitals

ARMOUR AND COMPANY

CHICAGO

SAVE MONEY ON YOUR X-RAY SUPPLIES

Get Our Price List and Discounts on Quantities Before You Purchase

HUNDREDS OF DOCTORS FIND WE SAVE THEM FROM 10% TO 25% ON X-RAY LABORATORY COSTS

AMONG THE MANY ARTICLES SOLD ARE

X-RAY PLATES. Three brands in stock for **quick shipment. PARAGON** Brand, for finest work; UNIVERSEAL Brand, where price is important.

X-RAY FILMS. Duplitized or Double **Coated—all standard sizes.** X-Ograph (metal backed) dental films **at new, low prices Eastman** films, fast or slow emulsion.

BARIUM SULPHATE. For stomach work. **Finest grade. Low price.**

COOLIDGE X-RAY TUBES. 5 Styles. 10 or 30 milliamp.—Radiator (small bulb), or broad, medium or fine focus, large bulb. Lead Glass Shields for Radiator type.

DEVELOPING TANKS. 4 or 6 compartments stone, will end your dark room troubles. 5 sizes of Enameled Steel Tanks.

DENTAL FILM MOUNTS. Black or gray cardboard with celluloid window or all celluloid type, one to eleven film openings. Special list and samples on request. Price includes your name and address.

DEVELOPER CHEMICALS. Metal, Hydroquinone, **Hypo, etc.**

INTENSIFYING SCREENS. Patterson, TE, or celluloid-backed screens. Reduce exposure to one-fourth or less. Double screens for flip. All-metal Cassettes.

PAPERS FROM THE MAYO FOUNDATION FOR MEDICAL EDUCATION AND RESEARCH AND THE GRADUATE SCHOOL OF MEDICINE OF THE UNIVERSITY OF MINNESOTA, covering the period of 1915-1920. Octavo volume of 695 pages with 203 illustrations. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $10.00 net.

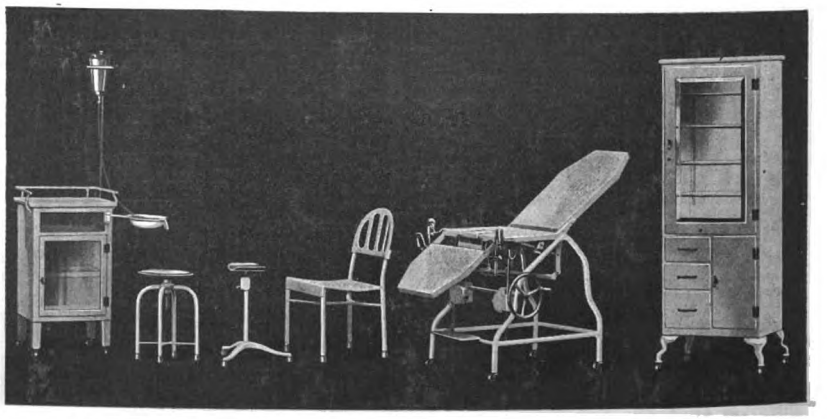
Largely this volume is made up of theses presented by graduate students in pursuit of degrees. Some are based on detailed clinical studies of the material furnished by the clinic and others are research in the pre clinical medical sciences. A few papers on subjects related to those discussed by the students are also presented by the faculty. A paper by John L. Busch on Ulcers of the Gastro-Intestinal Tract with Special Reference to Gastro-Jejunal Ulcers is of great practical value to both the internist and surgeon. According to the author, the stomach is an alkali manufacturer or preserver. "A function with which it is not generally credited."

A short article by William J. Tucker on Infections of the Kidney is also very practical. The writer points out the fact that in the treatment of colon infections the keynote of conservatism while in the coccus type of infection only radical surgery suffices.

Charles C. Palmer as a result of studies on the Influence of Partial Thyroidectomy in Pigs concludes that a degree of hypothyroidism insufficient to produce physical changes, markedly lowers resistance and impairs the functions of reproduction.

David M. Berkman in "A Preoperative and Postoperative Study of Diabetic Patients with Surgical Complications" reaches the conclusion that diabetic patients can often be relieved of disturbing and menacing conditions without undue risk by surgical procedures. In the mind of the reviewer the suggestion in this conclusion is timely in that he feels certain that many diabetics have in the past been doomed to suffering and in some cases premature death for want of surgical interference.

A most excellent paper is that by Albert C. Broders on "Squamouscell Epithelioma of the Skin." The paper is based on a study of 256 cases and is profusely illustrated. Of these cases 51.17% were preceded by some blemish such as a scab, wart, ulcer, etc.



Henry W. Woltman in his paper on "Brain Changes with Pernicious Anemia" concludes that the mental manifestations and terminal delirium in this disease are chiefly the result of the toxin.

Henry W. Meyerding concludes his short article on "Cystic and Fibrocystic Disease of the Long Bones" in part as follows: "Cysts may arise from local or general processes; Giant cells in moderate numbers, especially atypical forms, are not prognostic of malignancy; curetting and crushing in of the diseased wall is usually sufficient surgery; The microscopic picture is clear and should not be confounded with malignancy; The roentgenograph is fairly diagnostic but the history, clinical findings, examination of the patient and laboratory and roentgenographic reports should be included in making the diagnosis."

Irene Sandiford, in speaking on clinical metabolism, expresses the opinion contrary to Goetsch that the reaction after injection of adrenalin is "not indicative of the presence or absence of hyperthyroidism", but that the metabolic rate is the "only accurate index of the degree of hyperthyroidism and of the effect of either medical or surgical treatment of such cases."

A long paper by Lee W. Barry on "The Effects of Inanition in the pregnant Albino Rat" is especially interesting now that child welfare, birth control, eugenics and similar questions are so much in the limelight.

ABDOMINAL TRAUMA*

W. U. KENNEDY, M.D.
NEW CASTLE

The occurrence of traumatism to the abdominal wall without its perforation may and does cause injury to the contained viscera, varying in type with the severity and mode of application of the trauma. The principal type of such trauma is laceration of viscera, with the sequela of hemorrhage and peritonitis. Shock is the primary symptom, intensified by location of the injury above the umbilicus and by the volume of bleeding.

The diagnosis of visceral rupture, with its resultant indication for immediate laparotomy is ordinarily evident or will make itself evident by sepsis beginning in a few hours.

The treatment of such an injury by cleansing out the cavity, repair of injury and drainage needs no comment. It is proper to emphasize the necessity of regarding every considerable abdominal trauma as potentially mortal and wherever doubt arises, or with deepening shock or the beginning of sepsis, to give the patient the benefit of an exploratory laparotomy, the mortality of perforation or lacerating wounds increasing hourly at an appalling ratio.

The writer has observed a different type of traumatic peritonitis, of which there are no descriptions in the literature and which he believes to have been hitherto classed with the exudative peritonitis of sepsis. In a certain though low per centage of abdominal traumatic injuries the patient will quickly recover from the shock, there will be no evidence of sepsis, the pulse rate decreases, neither the red count nor the hemoglobin will decrease, the distension and pain lessen, dullness will not occur, and the whole picture shows amelioration, except that rigidity of the abdomen will persist and a subacute nausea remains. It may be summed up by saying that recovery from the acute symptoms has progressed to the point wherein one feels assurance of safety, but here that recovery halts, and after a more or less prolonged period and generally in a slowly progressive manner, the symptoms of nausea, abdominal rigidity and constipation increase until the picture is either that of acute obstruction or that of toxemia from absorption.

The gross pathologic changes found in these cases is that of an exudative peritonitis with agglutination of intestinal coils producing obstruction either (1) by constriction (by fibrous contraction involving the outer layer of the gut wall only); (2) by acute angulation; (3) loop obstruction by band; (4) mesenteric twist by a relatively heavy mass of adherent gut, aided possibly by fecal contents, turned on its axis by pressure of efferent distended gut; or (5) such a mass falling over another coil as a result of its weight and loss of peristalsis.

In the more acute type of this form of peritonitic adhesion, the serosal adherence is general, the intestine being uniformly and completely invested with a smooth exudate much as though glue had been poured into the cavity.

In the subacute and more chronic type, the adherence while relatively general, is accentuated by the formation of few or many distinct masses, some of which attain such size as to be palpable through the abdominal wall.

In these cases one observes neither adherence of omentum to gut nor adherence to the abdominal wall as is found in septic peritonitis, nor does the exudate break down into homogenous denucleated flakes, nor does the epithelium swell and break down as in sepsis.

This type rather closely corresponds to the acute hemorrhagic form of peritonitis, for at intervals may occur the brownish black dots which, according to Adami, are the result of chemical interaction of the sulphuretted hydrogen of the gut and the iron of blood pigment. But there are not the irregular laminations, nor the evidence of petechial patches, nor the irregular deposit of more or less disorganized clots, nor the deposit of lime salts, nor the early and wide formation of new capillaries. It is clearly differentiated from the chronic hyperplastic peritonitis in that hyalin degeneration does not occur or at least has not been seen after many months.

The sequence of pathologic changes seems to

*Presented before the General Meeting of the Indiana State Medical Association, Indianapolis session, September, 1921.

depend upon injury to the vasomotor mechanism through disturbance of the sympathetic, since there does not appear to be actual laceration of vessels and capillaries. At any event, the primary condition seems to be a congestive hyperemia of the serosa induced by vaso dilation incident to disturbance of the autonomic center. Whether or not there is effusion of leukocytes I cannot say, nor can it be absolutely certain that a low grade infection, not sufficiently virulent to set up an ascertainable septic reaction, exists, though the symptomatology negatives this and physiologic considerations do not require the presence of infection. Following the hyperemia a lymph exudate covers the serosa widely and completely except that it has not been noted on the stomach or the duodenum. The adhesions are smooth and firm, though nearly if not quite bloodless. They have a marked tendency toward radial contraction, but there has not been observed the condition known as peritonitis deformans which finally reduces the gut to a dense ball with the rest of the cavity filled with fluid.

Illustrative cases are Case 1—J. C., banker, age 45, was struck above the umbilicus by a thrown brick. He fell, in great pain and with severe shock which persisted for twenty-four hours. There was a silent abdomen, extreme abdominal rigidity, no temperature rise, little if any tympanites and no evidences of hemorrhage. He then sharply rallied and was apparently recovering without substantial injury, except a persistence of rigidity and moderate nausea. Gas came through after about twenty-four hours and later a fairly free stool. On the twenty-first day, because of steadily increasing nausea, persistent rigidity and the rather typical picture of mechanical ileus, the abdomen was opened, disclosing a widespread adherence of gut with sharp kinking by angulation in several places, so that determination of the actual place of closure was impossible. The coating of adhesions covering all the gut was smooth and fairly dense. There were no adhesions to the omentum or to the abdominal wall. The stomach was not involved nor the upper portion of the jejunum, nor was there fluid in the cavity. An attempt was made to separate the coils of gut by splitting off reflections of adhesions and filling in the gaps with omentum. After a long procedure, a fairly patent canal was obtained with a minimum amount of raw serosa. It was recognized then that adhesions would promptly re-establish. Resection of intestine was impossible and short circuit was impractical. He had complete relief for a few weeks, when the same progression of symptoms occurred and following attempt at short circuit he succumbed to a septic peritonitis. At the first operation the condition was deemed unusual, though not thought to be unique, but reflection and review of the literature impressed us with the belief that it might have been other than a septic type of peritoneal adhesion. At the second operation the conditions were so changed that no opinion could be formed. This man's history was carefully gone into and nothing was ascertained which might have any bearing upon the production of the primary adhesions at any time prior to the trauma.

Case 2—A boilermaker had an air riveting gun discharged while pressed against his upper abdomen. A typical shock of extreme severity followed, with abdominal rigidity and nausea. Following suitable treatment, he improved so rapidly that the idea of a visceral injury was abandoned. He complained mildly of continuing nausea and abdominal rigidity persisting over some three months, at no time being entirely free from discomfort, and latterly having a progressive increase of both these symptoms and of constipation which went on to almost a starvation phase with the evidences of the toxemia of intestinal stricture. In the sixth month a section disclosed almost the precise pathology of the first case; however a number of brownish black spots were seen studding the visceral wall and resembling small ink stains. After a separation of coils Cargile membrane was wrapped about all raw surfaces and suture lines not covered by reflected adhesions or omentum. Strict search was made for evidence of laceration of bowel or disease of organs of the cavity without result. The patient improved for a time, but was again developing the same obstructive symptoms when he died of a pneumonia. A post-mortem was obtained and the viscera removed. In no place could microscopic evidence of laceration extending through the wall be found nor any area of old hemorrhage with remnants of blood clot or pigment. The adhesive membrane had apparently obliterated all but traces of the serosa and few capillaries were found. The adhesive membrane was a fibrous sheet seemingly causing radial compression.

A third and fourth cases are not reported, for while the finding were much the same, a history of previous disease was obtained and definite local evidence was present of a previous septic peritonitis. And in each of these the outstanding symptoms were of abdominal trauma with shock, nausea and rigidity, the shock subsiding and the nausea and rigidity persisting with gradual evidence of intestinal obstruction. It seems quite possible that the previous condition had nothing to do with the peritonitis found, yet they are deleted because of the past history. In one case a mass of adherent gut was removed with recovery, the patient being finally lost sight of. In the other a short circuit was done with death from exhaustion and sepsis.

Case 5 was a young soldier struck in the abdomen by a piece of H. E. The usual symptoms of shock were present. After treatment in a

shock ward, he was sent back to my base hospital. Here the persistence of nausea and rigidity drew my attention. A fluoroscope being available, considerable study was done. Previous peritoneal disease was negatived by the history. The immediate case history after the injury was necessarily sketchy, but nothing in the record indicated sepsis or hemorrhage. Barium meals disclosed a normal stomach with emptying time of four hours, a normal cap but a hazy, illy-defined shadow of barium in the small gut, movable to some degree and with marked delay in reaching the cecum, and persistent retention in the gut. The colon showed no abnormalities. A section was done for the progressive toxemia and nausea and a short circuit. He was returned to the United States within a month in good condition. No information is available as to the later course of the disease and letters to him since have been returned.

It appears then that trauma may, by its action on the sympathetic, set up a type of peritonitis, non-septic in character, relatively slow in development but capable of producing almost irremediable damage. The diagnosis rests upon a history of abdominal trauma, with shock which is soon ameliorated, a persistent abdominal rigidity which continues after the patient should be free from symptoms, a persistent nausea, a more or less fixed doughy mass, obstinate constipation increasing in severity, a nearly silent abdomen with peristalsis abruptly terminating at a fixed place, when it can at all be elicited, and a gradual toxemia from intestinal stasis. The x-ray will show an illy-defined mass of barium in the small gut, usually somewhat movable, with definite delay in the head of the meal reaching the cecum, without the definite outline of a diverticulum and with a larger outline than a diverticulum, the colon showing no abnormality. Here parenthetically I may add that I have been impressed with the value of auscultation in this as well as other types of visceral trouble. It will reveal evidences quite equal to that gained by percussion or palpation and in this as well as other forms of obstruction, the silence is truly significant. In certain phases it is permissible to use small injections of pituitrin to emphasize blocking of peristalsis.

In the acute types an immediate laparotomy is indicated to establish the pathologic condition and to do such form of repair as will re-establish the fecal current. The widespread adhesions may be dissected loose and used to partly cover raw surfaces, supplementing these with omental flaps and Cargile membrane.

In the more chronic types a re-establishment of current would be difficult and in such instances short circuiting will be indicated and even re-section of masses of agglutinated bowel.

The possibility always exists of stretching of the adhesions and so long as obstruction does not exist to the point of closure, a waiting policy seems best. At least in my cases so little has been possible through intervention and the extensive operation so formidable that I would if possible defer operative procedure in these chronic types.

It had been my intention to discuss at this juncture certain other abdominal conditions such as appendicitis and hernia and they were announced in the printed syllabus. They are, however, reserved for another time.

The conclusions of these observations are:

1. That abdominal trauma may set up a type of peritonitis resulting in a pure form of generalized adhesion and without demonstrable laceration of intestine.

2. That as a result of such peritonitis an agglutination of bowel may occur resulting in varied form of obstruction.

3. That such a peritonitis may occur without intervening sepsis.

4. That such a peritonitis may be clearly differentiated from the septic type or the hemorrhagic type or the chronic hyperplastic type.

5. That such a reaction may be accounted for by damage to the autonomic center.

6. That a trauma followed by persistent rigidity of the wall and continued nausea is indicative of this type of peritonitis.

7. That such a group of symptoms plus acute obstruction or the increasing toxemia of stasis necessitates exploration.

8. That unless obstructive and toxic elements are definitely present and ominous a waiting policy is advisable.

9. Finally, in medico legal cases, an abdominal trauma, with persistent symptoms as herein described, may be regarded as a causative factor for the purpose of fixing liability.

DISCUSSION

DR. W. P. WILLIAMS (Lebanon): I quite agree with the doctor's general remarks that in acute abdominal trauma we should obtain early abdominal section to be sure of the conditions inside. As to the conditions which he has described, I have never seen a case. If I have I did not know it. When we have such a case presented to us of course the question is what to do with it. Since this trauma seems to be interfering with the nerve supply of the abdominal organs, probably any major interference in a surgical way to correct angulations, adhesions, etc., would be largely meddlesome surgery, because of the fact that the nerve supply to these organs is already so traumatized that we increase the trauma by surgical interference, and we may convert the case into a septic condition.

I am sorry I have not had the opportunity of seeing a case of this sort, and yet since the outlook for the patient is so gloomy perhaps it is well that many of us have not seen these cases.

I want to congratulate the doctor upon this original observation and report of cases of this kind.

DR. W. U. KENNEDY (closing): I want to say that the precise type of case in which this occurs are those in which we do not do a simple laparotomy, as the patients are apparently getting well and everything going smoothly. It is only after weeks and months that this condition develops, and then the question arises as to the primary cause. It is to put this particular type on record that I have read this paper.

STERILITY IN THE FEMALE*

G. B. JACKSON, M.D.
INDIANAPOLIS

Sterility may be broadly defined as that condition of the organism which renders the individual incapable of reproduction, although the term is usually limited to the impossibility of conception. The condition may be primary, absolute or idiopathic on the one hand, or secondary, relative or acquired on the other, and is of about equal frequency in the two sexes, this being a point of no little importance in practice as we shall later emphasize.

The essentials for fecundity in the female are: a normal ovum and a genital tract permeable to and not inimical to the spermatozooa, and physiologically fitted as host to the fertilized ovum for its transit, its implantation and its development in normal *situ* to viability. Given these conditions, and the deposit of normal male cells upon the vulva is sufficient to produce pregnancy.

Any condition which will impair these essentials of fecundity may produce sterility, *i. e.*, sterility in the broad sense of incapacity of reproduction. Such causes, as we have already mentioned, may be "idiopathic" or "acquired".

Graves[1] has written exhaustively of idiopathic sterility, and discussing "infantilism" in this relation says:

"Fetalism, a term introduced by Alfred Hegar, relates to a faulty or arrested development in intrauterine life, and is represented by conditions of aplasia, such as the absence of the vagina, uterus, ovaries or tubes."

The futility of medicine and surgery in these cases is self-evident.

Of "infantilism" he further writes that, as the term is used, it "presupposes that the individual has been born with a full equipment of genital organs, without mechanical obstruction to fetation, but that during childhood an arrest in development takes place so that in the childbearing age the organs retain certain characteristics of the prepubescent period."

This arrest in the development may be of the genitals alone in an otherwise normal individual, or it may be a part of a general hypoplasia or arrested development.

The same author says, as to the interesting question why infantilism is more common in women than men, that "the sexual apparatus of woman is so much more complicated than that of man that the chances of hypoplasia are very much increased", and quoted Hans Bob that "In general habit, in constitution, and in general mentality woman is half-way between man and child, and hence a certain amount of infantilism may be regarded as physiologic".

From the same source we read that if the infantile or hypoplastic ovary "be examined microscopically it will be found often that most of the follicles have not developed beyond the primordial state, and that there is a marked increase in connective tissue, as manifested by the thickened albuginea". According to Kehrer, this lack of development of the follicle apparatus accounts for the defective function of the ovaries on the ground of the late onset of menstruation, the frequency of amenorrhea and dysmenorrhea, of sterility and failure of sexual impulse, and vicarious menstruation.

Without discussing ovarian physiology at length, we may recall that the defect in ovulation has been explained on a mechanical basis, believing that the developing ovum either meets with too great a resistance from the thick albuginea, or has an insufficient internal fluid pressure of its own.

As for the role of the Fallopian tubes, W. A. Freund, the founder of our present knowledge of infantilism, describes the tubes of infantilism as being similar to those of the new-born in that they are "markedly twisted in a spiral form, especially at the uterine ends", and Bumm calls attention to a hypoplastic condition of the fimbriated structure. However, the infantile uterus is the most important structure in this subject and occurs in two distinct forms:

First, and very infrequent, the generally dwarfed or atrophic organ with normal proportions; second, the true type, of frequent occurrence, and presenting a narrow, short corpus with a relatively much elongated cervix and, as a rule, a marked flexion either anteriorly or posteriorly. At the point of angulation a cicatricial band has often been described, which Bumm has styled "callous stenosis" of the cervix. He is of the opinion that it is an important factor in the prevention of conception. (Graves.)

Involving, as it does, the various atresias of the tract, the vaginal defects which cause "*effluvium seninis*" (which cannot *per se* be considered a cause of sterility), the various toxemias and the fascinating problem—complex of heredity—surely the subject of infantilism itself

*Presented before the General Meeting of the Indiana State Medical Association, Indianapolis session, September, 1921.

1. Graves: Textbook Gyn.

is of sufficient theoretic interest to occupy the short time allotted for this presentation.

Of far greater importance, however, from a practical standpoint, is the acquired form of sterility. It is a deplorable fact that gonorrheal infection represents far and away the greatest causative agent in this class of cases. While statistics vary greatly as to the role of the gonococcus in this relation, we may judiciously accept the average statement of such authors as Neisser, Sanger, Findlay *et al.* that the gonococcus is active in at least 30 percent of cases. The adnexa need not be involved in order to produce sterility, for the condition may be due solely to the common endocervical gonorrheal lesion, although the adnexal extension is the usual pathologic cause, as so often seen in secondary sterility following childbirth, abortion, or mechanical interference in a subject of gonorrheal endocervicitis.

The mere mention of these facts impels me to digress a few moments in order to emphasize the culpability of the male as regards sterile marriages! Not only does he represent an equal part of the incidence of sterility, but he has been the infecting agent in the vast majority of gonorrheal wives. The indictment, however, does not rest here, for we must add thereto the cases due to syphilis—a not inconsiderable proportion of unfruitful wedlock!

In Leopold's Clinic, 25 percent of puerperal sepsis is gonorrheal. Puerperal infection of non-gonorrheal origin may also destroy fecundity, but not with the frequency of gonorrhea, for the tubes are much less often involved, although the endometrium is more often attacked. We know little, however, of true endometritis and less of its relation to sterility, excepting the very important endocervicitis. This is a frequent result of non-gonorrheal sepsis of the childbed and a potent and tractable cause of sterility. The condition may be readily corrected by the removal of the "plug of mucus" with gentle curettage and appropriate treatment.

Of auto-intoxication, Reynolds[2] says:

"My experience has not furnished me with conclusive evidence that general autointoxication from distant lesions is by itself a sufficient cause for sterility, most of the cases presenting hostilities in the secretions which required considerable local treatment, and which might have been due to other causes than biochemical alteration from disturbed health due to autointoxication; but the cumulative presumption derived from numerous cases leads me to accord much practical weight to this probability and to consider it important to eliminate all such conditions in the management of cases of sterility. This conclusion is reinforced by the experience of both experimental and commercial animal breeders that both good general condition and proper diet are essential to fertility, in both sexes. Animal breeders are emphatic about the advantage of a glossy coat, a clear eye, animated temper, etc., in breeding animals. These correspond, of course, to good complexion, bright eye and the general results of conditions of good elimination in the human race."

This, with the proper knowledge of the physiology of the sexual life and good sex hygiene, is very important. That many sterile women know nothing of sexual feeling is a matter of general knowledge.

Among other important and generally unrecognized causes may be mentioned:

Biochemical vaginal hostility, usually of bacterial and hyperacid origin; cervical hostility, as before mentioned (inflammation with acidity and mucous plug), and the tubal conditions so carefully studied by E. Ries and Reynolds.

In this latter connection I may emphasize the importance of a careful study of the normal flora and the chemical reaction of the genital tract in order to recognize and treat the deviations from the normal. This is certainly an important part of so-called "office" or "medical" gynecology. That much of the chemico-physiologic process in fecundation is beyond our ken no one will deny, and while many of this class of cases are therefore beyond our powers of cure at the present time, a careful and painstaking study of every case should nevertheless be undertaken.

Among the other causes of acquired sterility we may mention, with brief comment: genital tuberculosis and genital tumors (and here the peculiar primary sterility of the myomatous uterus is to be remarked, standing as it does in contrast to the others which act merely by their mechanical presence or by ovarian involvement). Many constitutional diseases and also chronic poisonings by different drugs produce sterility through intoxication of the germ cell, as do also the x-ray, radium, etc. Consanguinity and racial intermingling reduce fertility, and there are also cases which go to show that there may be an individual incompatibility of the germ cells. (Napoleon and Josephine present a classical example—she having had two children by a previous husband, he having one by a later wife, though they were together sterile.)

Malpositions of the uterus are not infrequent causes of sterility, and particularly is this true of the congenital types. Acquired retroversion may also tend to prevent conception and to produce abortion.

Finally, let us not forget therapeutic sterility as noted, for example, in the tuberculous, insane, eclamptic, thyrotoxic and other subjects.

In considering the care of this condition it would appear that the cases of congenital defect, *i. e.*, infantilism and fetalism, presenting as they do an impossibility of correction, are nevertheless due to preventable causes and therefore of

2. Reynolds: A. M. A., Oct. 11, 1919.

marked sociologic interest. The writer has in mind the well-known relationship of psychoneurotic defects (epilepsy, insanity, etc.), syphilis, alcoholism, and other chronic toxemias in the ancestry, to defective development (infantilism) in the progeny.

Naturally, the acquired forms of sterility are much more susceptible of prevention. Thus we are led to touch upon the field of moral and social matters, a field as yet almost untilled; that of genital disease prevention and the greater vista of moral and health teaching, eugenics—the great public health and educational problems.

In this connection permit me to call attention to the importance of "better obstetrics" in relation to this phase of the topic of sterility: *e. g.*, first, the influence of the prolonged pounding of a protracted second stage of labor upon the head of the child, resulting in brain injuries, psychic defects, epilepsy, etc. (when not kind enough to kill). The same is true of unskilled or extremely difficult forceps deliveries. Furthermore, and not less important, are the injuries to the mother which produce acquired displacements, erosions, etc., which when neglected in the puerperium cause sterility, as do also the childbed infections. Time does not permit a detailed discussion of obstetric care in this relation, yet we must impress the point that prenatal, parturient and postpartum treatment are in direct relation to the subject, and that "better obstetrics" should reduce these unfavorable results to a minimum.

Reynolds says: "Mistakes in the management of the marital relation are not infrequently by themselves a sufficient cause of sterility, usually by production of congestion and its results. Such mistakes in marital life are not usually perversions. They may even appear trivial, and yet if long persisted in produce important results or even changes in the organs which may demand operative treatment before pregnancy can be obtained. It is very disappointing for patients to travel, perhaps long distances, to see a specialist only to receive directions to try a change of habit and if this is unsuccessful to report again. This is a very frequent cause of sterility which the general practitioner ought really to be capable of detecting and correcting, so far as change of habit is concerned, before sending his patients away."

Following this statement he offers many helpful suggestions as to the difficulty of eliciting a history from these patients, and calls attention to the general lack of knowledge on the part of the general physician as to the injurious practices in preventing conception and the defects in cohabitation which tend to cause chronic congestion of the genitalia, and in conclusion says:

"This subject is evidently too complicated for brief discussion; but adherence to the principle that excitation without orgasm is a frequent cause of local disturbance and consequent sterility furnishes a safe guide for questions. When any one of these or other mistakes in coitus is remedied before it has been of long continuance, the mere correction of habit, or such correction in connection with minor local treatment, frequently yields a prompt pregnancy. When, on the other hand, the congestion which results from such habits has been long persistent it has not infrequently produced changes in the prostate, deep urethra or vesicles, or in the cervical or uterine mucous membrane, and even in the ovaries, which may require long continued treatment or even an operative correction before pregnancy can be secured."

Of signal importance in our work along this line is the endocrine system. Bandler[3] deals at length with this phase of the subject in his recent treatise and says in part, that menstruation is a constitutional affair associated with premenstrual phenomena, these latter being due not alone to ovulation, "but to the associated altered activities of the thyroid, the adrenals, and the pituitary gland, especially the posterior lobe". Further, that "the general symptoms of this recurring premenstrual period always show which of the endocrines is or are stimulated or inhibited, and thus the unstable member or members of the chain are disclosed".

While most of us will admit that we cannot as yet accurately define and deal with these broken links in the endocrine chain, nevertheless we can do much to determine the general classification of our cases and treat them accordingly upon a more rational basis. There is no doubt, as Bandler insists, that the majority of this class of cases, which he is pleased to term "curable", are subjects of relative uterine hypoplasia (I believe one might better say genital hypoplasia).

Now we have come to believe that the ovarian substance, the thyroid, the adrenal cortex and the anterior lobe of the hypophysis are certainly in close relation to the development and function of the genitalia, *i. e.*, a trophic relation. Furthermore, it would appear that the posterior lobe were in a close relation to dysmenorrhea, and that the placenta were in direct apposition to this pituitary activity.

Reasoning along these lines Bandler has treated this class of cases medically with good results, and rightly suggests the advisability of giving this form of therapy a thorough test before determining upon the surgical measures so often and possibly erroneously employed, viz., curettage, tracheloplasty, etc. He has published an interesting series of cases in "The Medical Clinics of North America" (II, 4) which though too small a number to permit of final conclusions, yet certainly go to show that

3. Bandler: **Textbook on Endocrines.**

"gland therapy" has a place in the study and care of sterility.

Duncan[4] has pointed out that in women "the age of marriage is the chief factor in the expencation of sterility" and that "fecundity is greater in women who have married between the ages of 20 and 24 years and decreases progressively to the menopause". He says that 95 percent of 1800 such wives bore a child within three years and "none proved sterile". While this latter statement cannot, in the face of the congenital conditions and the infections before marriage, be unreservedly accepted, nevertheless the figures suggest great possibilities along the lines of eugenics.

Omitting, for lack of time, detailed discussion of the purely mechanical and surgical considerations in treatment, I desire to mention the following points:

Proper surgical procedures for conditions of the abdominal organs should be done. They may be futile as to fecundity, but even so the pathologic condition is corrected, *e. g.*, misplacements and tumors of the uterus, cystic ovaries, salpingitis, etc. (Child[5] has published a very encouraging report of surgical cases.) The cervix should be cared for in all cases where it shows abnormality. The treatment will vary from simple dilatation and gauze packing for 24 to 28 hours to the Schroeder operation or amputation, depending upon the condition found. Solomons[6] believes that the cervix should be dilated in all cases of sterility.

There is at present some work being done (more or less experimental) along the lines of testing the patency of the tubes with oxygen, carbonic acid gas, or air. Artificial insemination, in cases of cervical interference, has been successful in some instances. Dickinson[7] has recently described an improved technique for deep or tubal insemination. This presupposes potency in the male, which is just as necessary as potency in the female, and which should be established in all cases before attempting to investigate the woman's fecundity.

To summarize, we would enumerate the following points of importance:

1. The role of the male both as to his own condition and his great responsibility as a causative factor in sterility in the female.

2. The vast scope of study necessary in all cases, embracing the entire field of genital and endocrine physiology and pathology, congenital and developmental defects, systemic intoxications, and even "mistakes in the management of the marital relation".

3. The wide field of preventive care, including eugenics, moral education and "better obstetrics".

4. The prognosis in general is good in young individuals and less so with increasing age and years of fruitlessness, but every case has a right to the best possible opportunity which care and skill can afford.

DISCUSSION

DR. ORAN ARNOLD PROVINCE (Franklin): At the outset it is well to remember that in all sterility of the female we must always test the male. Having ruled out the male it is essential to enter upon the examination of the female in a systematic manner. Here we may find upon inspection a urethral caruncle, tumors of vulva, deformities of vulva, gonorrheal warts, gonorrheal discharge, etc., either of which might interfere with proper sexual intercourse. We next should note the condition of the vagina with reference to tumor, stenosis, vaginal malformation, or vaginismus, that latter producing dyspareunia. It is very important to test the vaginal secretions and also the cervical secretions, because as you know the spermatozooa can only live four or five hours in the acid secretions of the vagina, while in the alkaline secretions of the cervix they have been known to live from one to seven days. Oftentimes we will find a plug of mucus in the cervix that causes trouble. In noting the reaction of the secretions of the vagina and cervix we may find that there is some erosion of the surface present, and this should be corrected, either by [illegible] or operative methods. An operative procedure which many follow is the amputation of the cervix in certain conditions. Some operators claim that they get best results from amputation and that sterility is not present in those who have been operated upon as often as those who have not been. And we have those on the other side who say that amputation of the cervix is not productive of propagation.

The next thing to be considered is the efficiency of the os. It is not uncommon to find a pinhole os either externally or internally. If the os is small it is very important that it be dilated and kept dilated in order that there may be free passage of the spermatozooa into the uterus.

We next examine the uterus by bi-manual palpation and sometimes find a large, soft, boggy uterus. In other words, a condition usually termed endometritis. This may be from faulty obstetrics, or from some source of infection, as gonorrhea, or from displacement of the uterus. It is not at all uncommon to find a retroflexion of the uterus, and as you know this is productive of sterility and should be corrected. In the condition of endometritis it is very necessary to curette the uterus and in all of these curettages it is important to use strict asepsis. Otherwise we may do more harm by spreading the infection. If the uterus is retroflexed there may be noted at the point of flexion

4. Duncan: Quoted by Burrage.

7. Dickinson: Amer. Jrnl. of Ob. & Gyn., Dec., 1920.

adhesions which make it almost impossible for the spermatozooa to get by. These conditions of retroflexions of course should be treated by the proper surgical procedure—as shortening of the round ligament, or whatever method you are in the habit of using.

At this point we must bear in mind fibroid and myomatous tumors, also such deformities as the bicornate uterus, the double uterus, etc., and last we must keep in mind the infantile uterus, which I think is rather common. I have noted this condition in a few instances when I have operated upon a patient for some other condition, the history of the patient having been that she was sterile all her life.

The next thing to note is the condition of the tubes, which may be large and inflamed, as in the different types of salpingitis. The most fruitful cause of salpingitis, as you know, is gonorrhea, which causes an inflammatory condition of the tubes and adnexa, the pelvis is oftentimes a mass of adhesions, so that it is difficult to differentiate the various structures. Some maintain that these cases of salpingitis can be benefited very materially by proper surgical procedure; but my own experience with gonorrhea, when it involves the tubes and surrounding adnexa, is that it is impossible to separate and correct all these conditions so that the patient will be able to bear children.

We should also note whether patients have a constitutional disturbance, like syphilis. Unfortunately, syphilitics are fairly productive of children. We note that people who are fleshy, who are extremely adipose, are in many instances sterile. In this class of cases proper diet should be given, and at the same time it is highly recommended that we give extract of lutein, thyroid extract, or ovarian extract. Many claim exceedingly good results, especially in these adipose women who have little or no flow at the time of their periods.

I think it would be wise for all of us physicians and surgeons to bear in mind that we should report all cases of gonorrhea and syphilis to our boards of health. If we do we will lessen the sterility 30 or 40 percent by getting these cases which are too poor for private treatment under the supervision of the boards of health where they will receive proper care and treatment.

DR. O. G. PFAFF (Indianapolis): It can be truly said that sterility is a question of seed and soil. We can do practically nothing to modify the seed and can only hope to correct a deficient soil. We may hope to correct certain abnormalities which operate to prevent, either ovulation, fertilization, or uterine tolerance of fetal growth.

Labhardt has investigated the connection between vaginitis and other disturbances of the pelvic organs and a very frequent coincidence was noted. In his opinion so-called vaginitis is undoubtedly extensively dependent upon ovarian dysfunction. Gonorrhea was excluded in all of his cases as far as possible by bacteriological examinations. Among about 200 cases at his disposal there were only a few without some factor (elicited in the history or demonstrated in the examination) indicative of ovarian dysfunction in the widest sense of the term. Vaginitis was repeatedly observed in connection with sterility. It is possible that not only a direct dysfunction, but a general disturbance of polyglandular cooperation is responsible for the onset of vaginal disturbances. This relationship between ovarian and vaginal disturbances it is suggested may be due to entrance of abnormal ovarian substances into the blood, or to an abnormal increase in the blood of normal ovarian products, or to an absence in the blood of those ovarian products which are normally present. Again, any combination of these factors is also to be considered as a possible factor in a special case.

Recent investigations have established an extensive influence of the ovarian function upon the uterine mucosa under various circumstances. Vaginitis is frequently combined with hypernutrition of the endometrium. Such cases are not purely local, but must be regarded as primarily referable to some disturbance of the endocrine ovarian function resulting in a change in the blood supply of the vaginal mucosa. Sterility may readily be thus assigned in certain cases of this form of so-called endometritis and vaginitis.

Sturmdorf in referring to the study of endocrinopathic sterility states that we must begin and end with the development and function of the ovary as a link which is reciprocally dominated by every other link in the endocrine chain. The domination of the endocrines on the functional activity of the ovaries manifests itself from fetal life throughout the reproductive period to the menopause. On the other hand, he states that just as the determination of sex is decided in the ovum before fertilization, so the future sterility or fertility of the individual is frequently an ovular preordination and is not governed by the laws of endocrinology.

Sturmdorf concludes with the statement that when we know *how*, *why* and *when* each of the internal secretions sitmulates or inhibits the ovarian function, then will the endocrine treatment of sterility merge from pure empyrism into a rational practice. When all is said that can be said to-day of the endocrines in sterility, the entire subject may be epitomized as a treatment in a condition of which we know little by a means of which we know less.

Many cases of sterility are of a purely mechanical origin. The ovum may be unable to

break through the thickened inflammatory peritoneum which imprisons it, or the occluded Fallopian tube refuses to permit its passage, or the abdominal mucosa of a disordered uterus refuses to tolerate the impregnated ovum and permit its normal development.

Our efforts to be successful must be directed to the correction of such evident defects as present themselves in certain cases. Many cases are very simple—a contracted cervical canal. Here a simple dilatation under anesthesia will often result in prompt fecundation. This result I have been able to achieve in a goodly number of cases.

In one case of pelvic infection and apparent sterility I removed a right pus tube and a left large cystic ovary. I then stitched the remaining right ovary into fairly close proximity with the left tube. This patient became pregnant soon afterwards and went to full term.

As a rule I believe that very little is to be expected from opening up occluded tubes. They soon close again in spite of the best care in suturing. I have tried this in numerous cases and have so far failed.

The correction of backward displacement very frequently is followed by impregnation. Occasionally the removal of a fibroid tumor, or other neoplasm, either from the mucous or serous side has resulted in a cure of sterility.

Brun tabulates 300 cases of sterility from all causes and it is interesting to note that about one-third of these patients suffered from the effects of gonorrhea, which at least suggests the possibility of a more or less efficient prophylaxis through educational efforts.

SOME ASPECTS OF RECENT SURGICAL PROGRESS*

WILLIAM E. GABE, M.D.
INDIANAPOLIS

In considering surgical advances of the last three years one is at once impressed by the fact that nothing new of epoch-making importance has been done, but there has been an unusual amount of benefit derived from experience which will undoubtedly be of much value in the actual practice of men who are progressive in their surgical work. By this time the worth while has been sifted from the chaff of the enormous amount of war material.

Anesthetics have played an important role. There is to be seen in the literature an increasing number of references to local anesthesia. Farr, of Minneapolis, is a foremost exponent of major operative work under local anesthesia. In almost every conceivable surgical operation he has made use of it. A special apparatus which facilitates injection, the extreme patience and gentleness necessary for the best results, and almost complete absence of post-operative discomforts and complications make operative work under this method highly successful. Gas-oxygen anesthesia in conjunction with local anesthesia as expounded by Crile is daily having a wider range of usefulness. Its use by Crile in every phase of surgery has popularized it generally. It is, however, the experience of most men that its use in the upper abdomen is decidedly limited, except possibly in the operation of gastro-enterostomy where much of the work is done outside of the abdominal cavity. The inability of securing good relaxation and the necessity of an expert for administration are its two great limitations. Stanley has pointed out a wide range of usefulness enjoyed by spinal analgesia in upper abdominal work. He reports sixty-eight cases with no difficulty in securing absolute relaxation of the abdominal walls, no shock, and scarcely any vomiting. The great value of spinal analgesia in work upon the lower extremities and in superficial operations such as hernia, and hydrocele, has long been recognized, especially for use in the aged. It is not, however, without its dangers. The synergistic action of morphine and magnesium sulphate as demonstrated at the Presbyterian Hospital in New York and described by Gwathmey, promises to give better and safer relaxation than has heretofore been obtainable, regardless of the type of anesthesia, but especially that of nitrous oxide in conjunction with oxygen.

The matter of abdominal incisions commands some interest. The war demonstrated every kind of wound of the abdominal wall that required in many instances bizarre and unusual incisions for proper work. Every man of experience in this work found no greater number of herniæ following these cases and no crippling of the abdominal wall from the incision of muscle and fascia in all directions and planes. The conclusion is drawn that the old ideas of adhering closely to orthodox abdominal incisions are fallacious, and unnecessarily cramp the operator in his field. Farr has recently called attention to the trans-epigastric and trans-rectus incisions for work upon the stomach and gall-bladder—an incision widely used in the clinic at Lakeside Hospital in Cleveland. Tymmis has discussed the question of the choice of incision in acute abdominal conditions. Here undoubtedly the incision paralleling the right costal border and dividing the right rectus transversely and continuing downward parallel to the outer rectus edge is the one of choice. It easily permits general exploration, for through it the colon, pylorus, almost all of the stomach, head of the pancreas, gall-bladder, gall ducts, right kidney, duodenum, appendix and right pelvic organs can be examined and operated. It is truly the

*Read before the Seventh District Medical Society at Franklin, July 6, 1921.

most generally useful incision known for the abdomen.

The treatment of peritonitis has lately attracted attention because of some remarkable results obtained at Crile's clinic. His method of treatment he insists upon in a very definite and detailed way. Through his method, out of a series of 13,415 laparotomies, he has reduced his mortality in cases of acute appendicitis alone by over 67 percent. In a personal communication he recently stated that he no longer fears any but the streptococcus types of peritonitis. Briefly his method of treatment is—

(1) Adequate surgical drainage under anociation.

(2) The sitting position continuously from the time the diagnosis is made through the operative and post-operative course.

(3) Vast hot packs over the entire abdomen extending from the nipples to below the groins and well to each side, maintained *hot* twenty-four hours out of the twenty-four.

(4) Assimilation by the patient of at least 4000 cc. of normal salt solution subcutaneously every twenty-four hours.

(5) Morphine hypodermically until the respirations are between 12 and 14 per minute, which rate is to be held until the patient is out of danger.

Supplementing these specific factors are others such as an accurate clean cut operation done with sharp dissection and gentle manipulation and the free use of gastric lavage post-operatively. The use of Fowler's position, heat, morphine, and fluids is nothing new in regard to the treatment of peritonitis, but used in the above prescribed specific way they almost assure the recovery of any but a streptococcus variety of peritonitis, in Crile's experience.

Work upon the origin and nature of malignant tumors has still failed to throw any light of striking importance on the subject. Ochsner has lately urged that every precaution be taken against cancer infection, although its infectiousness as yet be unproven, and has called attention to its occurrence almost exclusively in situations in the body exposed to outside irritation. Pennington's recent article summarizing old and new theories concerning cancer represents an immense amount of work. Starting with Adam's parasitic theory in 1801 he calls attention to a wide range of supposed causes as a manifestation of systemic disease and hence to be treated by mercury, hemlock, venesection, infection with malarial blood and even syphilitic blood; also rheumatism, tuberculosis, being a first-born child, thyroid overwork, high temperature of food, drinking unboiled water, alcohol, excess of salt, and so on. Some theories are genuinely amusing as when Schüler's much-talked-of golden yellow organisms proved to be cork cells from the material in which the specimens were mounted. Pennington seriously questions whether there is an *only* cause of malignancy but believes, with Rohdenburg and Bullock, that the wide distribution of cancer in nature speaks for the possibility of its being dependent on general biologic phenomena. As Bashford points out, even the lowly oyster can harbor a genuine cancer.

Blood transfusion is daily becoming a more useful and more used surgical operation. Compatibility tests of the blood of the donor and recipient are imperative, and disregard of this step is nothing short of criminal negligence. Without doubt the citrate method attracts by far the greater number of adherents. It is easy to do technically, it requires practically no special apparatus, it does not involve the destruction of a vein in donor and recipient with the necessity of local anesthesia and a minor operative procedure—the vein is merely punctured with the needle and is not destroyed by tying off. Haste and speed are not necessary because coagulation is not to be feared. Lastly, and most important perhaps, is the ability by the citrate method to transport the blood from donor to recipient. In other methods the donor and recipient must be in the presence of one another. By the citrate method with perfect ease and safety a recipient may receive the blood from a donor 100 miles or more away. A sufficient number of investigations have shown that the amounts of citrate used are so small they play no role whatever in the chemical and clinical properties of the recipient's blood. According to Richet, Brodin, Saint-Girons, Lewisohn, Pemberton and others, harm from this method of blood transfusion is due to either a too rapid injection or a too great quantity given at one time, both of which factors would hold true in any other method. The incidence of chills following the citrate method may be somewhat greater than by other methods but the method is not accompanied by any mortality or much additional morbidity, according to the recent reports of 100 transfusions by Fleming and Porteous, 200 by Lewisohn and 1036 by Pemberton.

The subject of post-operative parotitis has attracted the attention of several writers, notably Collins and Deaver. This rather serious complication follows ordinarily abdominal operations upon the female. Prophylaxis by means of cleaning and keeping the mouth moist, hypodermocylsis, chewing paraffine, etc., often fails and infections follow. The usual treatment consists in free incisions and packing with moist gauze. This is not always satisfactory. Crile recently has found that crucial incision of the posterior capsule of the gland cures most cases. This incision is made by sense of touch entirely and is necessarily a delicate procedure because of important posterior structures that might be harmed. The resulting relief of pressure with

good drainage established rapidly terminates the inflammation.

Thyroid surgery continues to play a leading role in major operative work. As Ballin has pointed out the outstanding question concerns the *correct* treatment of the many cases of exophthalmic goitre. A patient whose thyrotoxic symptoms have developed in a goitre of some standing (the so-called secondary type) can be operated in a radical way with almost certain safety even though running a high pulse, but not so with the patient whose toxicity has developed with her goitre from its onset. Preliminary ligation is unquestionably indicated as a precursor to radical operation—a point which, as Lahey forcibly asserts, need not be drummed into the experienced operator because he has long ago learned his lesson by a disheartening mortality following primary operation. The Mayos consider a ligation not only a preparation toward radical operation but as a means of judging the patient's ability to stand further work as evidenced by their reaction to one or more ligations. Instead of ligation Ballin uses a continuous suture through the gland substance in an effort to cicatricize the tissue. He finds this usually curative and accompanied in over 200 cases by no mortality whatever. Refinements in technique have largely done away with injury to parathyroids and recurrent laryngeal nerve and with laryngeal huskiness. Lobectomy versus partial lobe resection is still a much discussed question with perhaps a preponderance of favor at present being with the adherents of the partial resection operation. It undoubtedly protects the posterior structures best, gives a better cosmetic result, and does away with the hypertrophy of the opposite side that sometimes follows lobectomy, as it must be borne in mind that in paired organs removal of one causes the other at times to undergo hypertrophy. The estimation of basal metabolic rate and the adrenalin sensitization test are both of the utmost value when correctly done. The Mayos consider the estimation of basal metabolic rate as almost a specific indicator in hyperthyroidism when fevers, diseases of the pituitary and inanition are ruled out. It is unlikely that any unanimity of opinion will ever be reached concerning the correct anesthetic indicated in thyroid surgery. Ochsner, Eastman and Lahey use local anesthesia, the Mayos straight ether, while Crile uses gas-oxygen in conjunction with local anesthesia.

In gall-bladder surgery the techinque of exposure has come in for some attention. By the use of the incision spoken of earlier in this paper, the placing of a pillow under the right flank, the correct position of the operating table and the introduction of a gauze pack between liver and diaphragm as suggested by Masson, thus pushing the liver down, exposure is greatly facilitated and difficult operations upon the ducts and gall-bladder itself are rather easily done even in the usually fat type of patient. A number of surgeons have recently emphasized the importance of a working knowledge of the rather common anatomical anomalies that exist in the relations of the gall ducts and blood vessels. Babcock has called attention to the frequency of chronic cholecystitis complicating cardiac lesions, this being the cause of the frequent symptom of "indigestion" appearing in these patients. A rapid operation with gentle manipulation reveals the gall bladder or appendix at fault, and removal relieves the patient's pain, palpitation, flatulence or eructations. Babcock advises against elaborate operation with unnecessary exploration and finds the correctly done procedure is perfectly safe in this type of case. Smithies has called attention to the fact that out of 1000 examples of gall bladder disease 93 had pathological heart conditions. The present tendency is to favor removal of the gall bladder rather than simple drainage of that organ when diseased, as statistics from many sources continue to show secondary operations necessary in the drained cases. Ochsner, however, contests this view. He leaves the organ in, sewed to the peritoneum and fascia and packs its cavity with gauze. The latter point is important, as when he drained with the tube he found secondary operations frequently necessary. Roentgenologists, through improvements in technique, are becoming more able to give accurately a positive diagnosis of existing gall stones. Undoubtedly the greatest step forward in the study of gall bladder disease of modern times is the magnesium sulphate test first suggested by Meltzer of the Rockefeller Institute and whose practical details were worked out by Lyons of Jefferson University. In this test the injection of magnesium sulphate through an Einhorn tube into the duodenum causes a relaxation of the sphincter of Oddi with a subsequent flow of bile in three distinct parts —the first from the common duct of thin syrupy consistency, the second from the gall bladder of thick ropy consistency and of a dark color, and the third again of thin consistency and of light straw color from the liver itself. This test has been used innumerable times all over the country and has been found to be of great value especially in diagnosing cholecystitis and distinguishing between it and obstruction of the cystic duct. There have, however, been a number of reports from careful investigators who feel the procedure has been greatly overestimated and who even deny the ability of anyone to obtain the bile in normal cases in three distinct parts. The test may be done by anyone without special apparatus except the tube. The experience of the average clinic agrees with Crile, who found out of 33 diagnoses of cholecystitis by means of this test, 30 were confirmed by operation and out of 60 gall bladders ruled out

as normal by means of the test, only six mistakes were found at operation upon other abdominal organs subsequently. The error in diagnosis is about 10 percent. Incidentally the magnesium sulphate injection into the duodenum offers a most excellent treatment for catarrhal jaundice, according to its originator, Dr. Lyons.

Time does not allow a further account of additional important surgical advances. The magnificent progress made in chest surgery recently has not even been mentioned, nor has our gradually standardized method of nerve suture as developed by Dean Lewis. Practically everything we know of surgery of the heart is of post-war compilation as is also true of our newest methods of bone grafting. It is to be hoped that careful work and fruitful experience will teach us to be still more conservative in our daily operative work and will open further channels for the development of new ideas and progressive methods.

A CASE OF BEZOLD'S MASTOIDITIS PRECEDED BY THIRTY YEARS OF MIDDLE EAR SUPPURATION*

C. NORMAN HOWARD, M.D.
WARSAW, INDIANA

On June 22, 1881, Friedrich Bezold (an otologist of Munich) in an address before a medical society in Germany, described what has come to be known as the Bezold type of mastoiditis. The following month this address appeared in print. From a perusal of it one gleans the salient fact that a suppurating mastoid may elect to give way at the tip and permit a flow of pus into the soft structures of the neck. That, then, is the Bezold type of mastoiditis.

I would like you to visualize with me the tip of the mastoid, perhaps more technically called the mastoid process. On the outer surface of the tip we find the bone rather thick and covered with the tendons of the sterno-mastoid, splenius capitis and trachelomastoid muscles. While pus can go through the bone of this external surface, yet it is very difficult, and even if accomplished its journey to the neck is practically stopped by these muscle insertions. Now let us look at the inner surface of the tip. Here it is different. Here we have bone that is smooth and not so thick. The digastric fossa or groove, sometimes called the incisura, occupies a large part of this surface. It is this groove that lends itself to the attachment of the posterior belly of the digastric muscle.

Let us now consider the mechanics of such a situation. Suppose we have pus coming through the bone of the inner side of the tip. It will tend to continue its journey—because that is the nature of pus. This particular journey is full of potential mischief. You see, the easiest way is down the neck internal to the three muscles attached to the external surface of the tip. It can go backward to the median line and it can go downward clear into the thoracic cavity.

Bezold states that the patient may recover after some months if the pus has been gotten rid of by deep incisions and drainage. In other cases there is a fatal outcome due to exhaustion, involvement of the spine, edema of the glottis or spread to the thoracic cavity. It is therefore seen that, while the Bezold type does not present the *cranial* dangers of other forms of mastoiditis, it is fraught with menace peculiar to itself. Fortunately this Bezold type is now rare. The reason for this you may have already conjectured; but I wish to emphasize this point after a description of the following case:

When patient O. B. was five years of age diphtheria visited the family. His three sisters were very ill with it and one of them died. He passed through the ordeal with what was probably a mild attack of diphtheria, nothing being noted but a "sore throat." About this same time, history has it, a discharge of pus appeared from the left ear. This discharge has kept coming and clearing up again through a span of thirty years—he being now 35.

About two years ago the patient contracted the flu. Otherwise he has weathered along very well, except for a trying time of a year on crutches following a leg fracture. He is a successful business man, and has borne his recurring ear discomfort with the same optimism which has carried him to a high place of regard in his own city and elsewhere.

Some years ago there was a mass removed from the left external canal. Probably it was a polypoid growth, resulting from the long years of intermittent streams of pus going by, leaving the trademark of its ugly touch by the way. At those times, when the pus came through the left drum and rolled out to the pinna, it did so without ear pain, although there was an occasional slight pain below the left mastoid. Thus, for thirty years.

On November 5, 1920, something more began to happen. Pain and swelling occurred in the neck and grew worse and there were fever, loss of appetite and pain in opening the jaws. On November 10, 1920, Dr. Cripe, his home physician, and Dr. Landis, a relative, brought patient O. B. to our Clinic. He was put through routine x-ray and laboratory examinations and tests. You will be interested in the local findings. There was pus on the floor of the canal of the left ear and a granulomatous, polypoid mass in the anterior superior portion of the canal. The drum was not reddened, neither was there bulging of the posterior wall. Whisper was heard at one foot with this left ear. Left

*Read before the Section on Ophthalmology and Otolaryngology of the Indiana State Medical Association, Indianapolis session, September, 1921.

side of neck was swollen. The greatest pain on pressure was two and one-half centimeters below tip of the mastoid; some pain on pressure over tip but none over antrum. That is, patient's main distress lay not in the ear and not in the mastoid, but in the soft structures of the neck.

I operated the next morning. The entire mastoid cavity was found packed with a mass of old, partially dried, cheesy, foul-smelling pus, with fresh fluid pus flowing into it from the antrum. No mastoid cells were left—simply a mass of pus from the outer to the inner shell of the mastoid bone. After this was cleaned out, an opening was found in the inner plate of the tip of the mastoid leading out into the soft tissues of the neck. A probe passed easily through this hole to two centimeters below tip. Incision and blunt dissection did not disclose any pus in the neck at that time; but later a large quantity of pus was obtained from the neck. A generous myringotomy was made in the left drum, through which came thick, creamy pus. The polypoid mass in the canal was curetted away.

It was about two months later that patient resumed charge of his business—feeling very well. But it was not until a month after that that the last tube was removed from the neck.

The tonsils, being diseased, were removed this summer.

There is still a little discharge from the external canal, and a slight amount from a small remaining opening in the mastoid, leading back to the antrum. One might feel tempted to do a radical mastoid, were it not that the patient's hearing in this affected ear is much better than it has been for years. In fact his hearing now is normal, that is, 20/20th whisper in each ear.

Frank H. Baker, pathologist for our Clinic at that time, found something out of the ordinary in the germ content of the mastoid cavity. He made elaborate tests in regard to the dominant organism. The gist of the matter was that he considered it a diphtheroid, although it was Gram negative and motile; whereas, according to Stitt, the diphtheria family, including pseudo-diphtheria commonly called diphtheroids, belong to the Gram positive non-motile variety. A culture of this organism was also sent to the Gradwohl laboratory in Chicago. The first report received from Dr. Gradwohl was that he found an irregular staining long bacillus and he was not sure of the family to which it belonged. But after the Gradwohl laboratory had made various tests, they also came to the conclusion that it belonged to the diphtheroid group. On the other hand, another good pathologist claimed that such things could not be. It would require more boldness and greater knowledge than I possess for me to enter this bacteriological discussion, but I very much hope that some bacteriologists present may take it up. Nevertheless, the central fact remains that there was a peculiarity about the morphology and actions of this organism, which my patient had harbored for thirty years, which marked it as something different from the rest of its kin. This brings up an interesting point which will be included in the summary of this paper.

Bezold has been quoted as saying that twenty per cent of all cases of mastoiditis are of this type. This was, of course, some years ago, Bezold having lived from 1842 to 1908. In some of the recent text-books it is mentioned as a rare or unusual condition. In trying to clear up the question of the actual latter-day percentage of occurrence, H. J. Councilor made a search for me in the Surgeon General's Library at Washington and wrote me, in part, as follows: "I have made a thorough examination of the literature indexed for the past twenty years in English, German, Italian, French and Spanish, dealing with mastoiditis, in an attempt to find something dealing with the relative frequency of the Bezold type. Although I found a number referring somewhat at length to the differential diagnosis, yet in no article were definite percentages mentioned." In reply to a letter of inquiry, Dr. Joseph Beck of Chicago stated: "I am pleased to report that in my experience of twenty-five years, during which time I examined and operated on more than three thousand mastoid cases, I have just had eleven Bezold's type." That, you see, would be less than four-tenths of one per cent. The reply received from Dr. H. P. Mosher of Boston said: "One per cent or even less." Dr. Charles W. Richardson of Washington wrote me as follows: "Bezold abscess in my hands has been about one-tenth of one per cent of mastoiditis. I consider it the rarest of conditions. I have always looked upon it as a type of perforation which took place in neglected and undiagnosticated abscess of the mastoid, particularly involving the lower cells and the tip. Bezold described these conditions some thirty years ago when the mastoid operation was done as a last resort, and therefore they were more frequently observed by him at that time than they are at the present time. With the early operation now there is no time for the development in the perforation of the tip in the digastric groove."

SUMMARY

1. It is interesting to note the long period of thirty years' infection in this patient; apparently starting from a mild attack of diphtheria.

2. Given a thirty years' local lodgment of diphtheria bacilli, let us speculate: Might these diphtheria organisms gradually change their characteristics (such as staining qualities, motile possibilities, etc.) just as a group of people isolated from outside influences might gradually

diverge from the original stock? The bacteriological findings are very interesting with this thought in mind.

3. Also, consider the minor role the pus-filled mastoid played in the local subjective symptoms of the patient.

4. The post-operative gain in weight (sixteen pounds more than at any prior time), with a splendid increased feeling of well-being, is probably an expression of systemic relief from a long harbored focal infection. The marked improvement in hearing is gratifying.

5. The now rare occurrence of the Bezold type (less than one-half of one per cent of all cases of mastoiditis, as compared to twenty per cent in Bezold's time) is largely due, as Dr. Richardson said, to the earlier surgical interference in mastoiditis by the modern otologist.

DISCUSSION

DR. E. J. LENT (South Bend): This type of descending abscess readily divides itself into three groups. This division is not arbitrary, but rather conforms to the anatomical configuration of the parts and to the insertion of the muscles at the tip of the mastoid.

In one group would be included those cases which perforate the tip in the region of the sterno-mastoid where the muscular tissue is dense; the course of this type of perforation is rather slow. The determination, if early drainage is instituted, is always recovery. There is one condition characteristic of this type of Bezold's perforation, and that is that the swelling is just at the tip of the mastoid. Another characteristic is that in very many cases you cannot palpate the tip of the process at all.

In the second group would occur those perforations where the pus drains into the tissue between the muscles, following the fascial apertures. This is the most fatal type of Bezold's mastoid. In this form of perforation the pus may burrow down as far as the clavicle, even to the roof of the pleura and as far back as the cervical vertebra.

The third group includes those cases where the abscess perforates into the muscular substance of the digastric. The course of this is slow and is very difficult at times of recognition. It is characterized by deep brawny swelling of the neck far forward, sometimes reaching the arch of the pharynx. Bezold records one case of perforation in the belly of the digastric, the abscess eventually draining into the pharynx. The patient recovered.

Fortunately these abscesses do not occur very often in infants or young children, due largely to the fact that the mastoid is not developed before the third year. However, children do have subperiosteal abscesses, which are higher up; the pus making its exit through the petro-squamosal suture.

As to the treatment of these cases, it is obvious that a radical exenteration of all mastoid cells should be made. The perforation in the tip should be located and enlarged, a guide passed down into the pus chamber and counter drainage established.

In a chronic case such as the doctor has here recited, permanent safety of the patient is enhanced by a radical procedure. The fact that the patient's ear had been draining for thirty years, no matter what the type of infection, would indicate a radical operation.

DR. HARRY BOYD-SNEE (South Bend): I have listened to Dr. Howard's paper with much interest, but I cannot accept it as covering the whole subject of the complication which is designated Bezold's type of mastoiditis. I must inject into this discussion consideration of the petrosa as a structure which can harbor the primary focus of infection in association with mastoid involvement; or it can exist quite disassociated from the mastoid structure. I have observed this complication in direct connection with the primary focus located in the petrous portion of the bone, and the connecting tract was found in an erosion in the wall of an infected terminal petrosal cell situated deep and beyond the mastoid; I have also noted it as a post operative complication in a case in which complete mastoid exenteration and complete tip and digastric plate resection had been done, and the direct connection was found in an erosion in the jugular plate of the petrosa. With this knowledge the operator who encounters Bezold's complication without any manifest defect in the digastric plate, will not hesitate to penetrate and explore the petrous portion.

DR. CARL MARION SAUTTER (New York City): Concerning the Bezold type of mastoid, I have had a few cases, and as I remember, most of them were due to a virulent type of infection. Two cases occurred where there was chronic suppuration and a radical mastoid was performed at once.

One case that I particularly remember that gave me considerable trouble, was the third type pneumococcus infection. That is an infection and organism that will cause more destruction and more breaking through of bone than any other type, and will do so very quickly sometimes. This infection was formerly known as the capsulatas streptococcus, but this is generally conceded now to be a misnomer.

Concerning diptheroid infection I cannot say much about that, but we do know that we get all kinds of infections in the mastoid. We even have the Vincent's spirillum, but these infections are more apt to be benign.

As one of the speakers has said, I believe it is quite true that the Bezold type is found less often than it was formerly, because of the early

diagnosis and the early operative interference in the mastoid.

DR. JOHN F. BARNHILL (Indianapolis): Bezold's type of mastoid abscess is, in my experience, not so frequently met with as reported by Bezold, nor so rare as quoted in the experience of Beck and Richardson. There can be little question but that the disease is less common now than twenty years ago when I saw and operated many cases. However, judging by the number I have seen and continue to see, I could not agree that the affection should be regarded a rare one.

While Bezold's abscess is always a late manifestation of mastoiditis, I have never known of a case occurring as late as thirty years. Indeed I have never witnessed its occurrence in a chronic case. It occurs usually from two weeks to two months after the onset of the mastoiditis, and depends largely upon the severity of the disease and the character of the mastoid cells. It happens only in cases where the cells are large at the mastoid tip and the bony cortex thin toward the diagastric fossa. When the cortex is thin above the attachment of muscles to the mastoid tip the perforation of bone takes place behind the ear and the pus travels upward, doubles the ear forward and produces the well known post-aural abscess. When the perforation is into the diagastric fossa the pus travels downward along the corotid sheath; there is hardening of the structures of the neck below the ear, the neck is stiff and painful to pressure, but the mastoid region itself usually remains normal in every way. Bezold's abscess is an example of surgical neglect. It would rarely occur if mastoiditis is early diagnosed and early operated.

DR. C. NORMAN HOWARD (closing): One would naturally think of the advisability of doing a radical mastoid. My reason for not doing it was that at the time it was an acute condition. I was anxious to do for this man the immediate necessary things, and if possible to get him through with no lessening of his hearing, or with perhaps an improvement. This we accomplished and his hearing is now perfect with that ear.

Of course we have not been idle from the medical standpoint; ringing the changes on various local antiseptics. His tonsils showed a possibility of making trouble, and we took them out. In other words, what I am trying to do with that man is to save his hearing, and if it comes to pass that other symptoms develop, we will probably have to do something further in order to save his life.

SHALL WE ADVERTISE?*

E. G. REYNARD, M.D.
Union City, Ind.

In presenting a paper on this subject, I do so believing we can well afford to rest from the usual scientific papers read and discussed at these meetings, and consider some of the principles of the profession which are now being endangered, but which have prevailed since the introduction of medicine.
